One of the first models of the life cycle is presented by Chandler (1962) who has identified four stages of the evolution of the organizational model. Greiner (1977) followed him by presenting one of the most famous models characterized by evolutionary phases and periods of revolution or organizational change. Then we witness a proliferation of models according to the life cycle theory which mostly remain without empirical efforts. Most CVO models adopt the naming of stages or phases of the life-cycle (Hanks et al, 1993; Adizes, 1988; Smith, Mitchell and Summer, 1985; Miller and Friesen, 1984; Quinn and Cameron, 1983); others make use of those growth stages (Galbraith, 1993; Kazanjian and Drazin, 1990; Scott and Bruce, 1987) or development stages (Dodge, Fullerton and Robbins, 1994; Scott and Bruce, 1987; Churchill Lewis, 1983). We choose the name of the models according to the CVO phases because these models have been verified empirically. These phases are the CVO (Dodge, Fullerton and Robbins 1994: 123): “sequence of events that describe how things changeover time; a hierarchical progression that is not easily reversed and a composite of a board range of organizational activities and structures ".

The evolution of organizational models describe specific periods of development organization while those with lesser number of phases generally combine periods of development. Miller and Friesen (1983) proposed a five-phase model that is applicable to any organization that seems most appropriate for our research.

Birth (the existence, entrepreneurial phase). This phase is characterized by a formal structure (Mintzberg, 2003, Lippitt and Schmidt, 1967) under the direction of "One man show" (Chruchill and Lewis, 1983; Scott, 1971). The most important thing to is achieve results, research gains and customer satisfaction (Adizes, 1988).

Growth (the growth, survival). This phase enhances the response to market needs by seeking financial resources, product diversification and the development of distinctive competencies (Quinn and Cameron, 1983; Lippitt and Schmidt, 1967). The organization seeks to adapt to a complex environment and mutations (Scott, 1971). The search for stability and resolution of internal issues are the primary concerns during this phase.

The maturity (stability). The profession of management is installed and the commitment of the members to stability is strongly felt (Mintzberg, 2003). The decisions and objectives are centralized (Miller and Friesen, 1984; Greiner, 1977). Maintaining the organization makes use of formal structures and institutionalization of procedures (Kimberly and Miles, 1980).

Revitalization (recovery). This is the stage of renewal and search for solutions. The organization values innovation and creativity (Lester, Parnell and Carrahar, 2003; Mintzberg, 2003; Miller and Friesen, 1984). To respond to the heterogeneity of the market, the manger multiplies product lines, and diversifies the market and the directions.

The decline (death). This is the tension and problems phase. The inability to resolve conflicts, internal problems or meet external demands led to the eroding of the organization's life.

We will below study the life-cycle of the Tunisian agribusiness organizations on the basis of five criteria proposed by Lester and Parnell (2008) and Lester, Parnell and Carrahar (2003). These criteria are (Structuring; Specialisation / differentiation; Information processing; decision making; formalization). These authors developed five items each relating to a phase for each criterion. We will, therefore, examine the 25 items.

Results

The data is based on a convenience sample. We provided a questionnaire survey administered in an assisted manner. Our sample includes 256 leaders in all of small and medium enterprises operating in the food sector. The measurements are made by using the Likert scales of 5 points; whose validity and reliability were confirmed in previous studies.

We interviewed leaders on the pace of the evolution of their organizations, the age of their businesses, and the ability to identify their evolutionary phase in a simple categorization. The life-cycle of the organization is measured by the Lester and Parnell measuring scales (2008). A typological analysis allows to diagram the characteristics of the life-cycle of Tunisian organizations.

The Characteristics of the Life-Cycle of Organizations

The questionnaire was administered to four hundred managers operating in the Tunisian food industry in small and medium enterprises. The response rate is 64%. 42% percent of respondents are male. More than half of the companies visited were aged over thirty years. One quarter of the respondents exceeded 11 years'service. Thus, our sample is sufficient enough to develop our scale.

Most companies visited belong to the oil and fats (19.5%), other food industries (14.8%) and sugar and derivatives industries (13.3%). Our sample is industry quite diverse which helps to specify the Tunisian agribusiness.

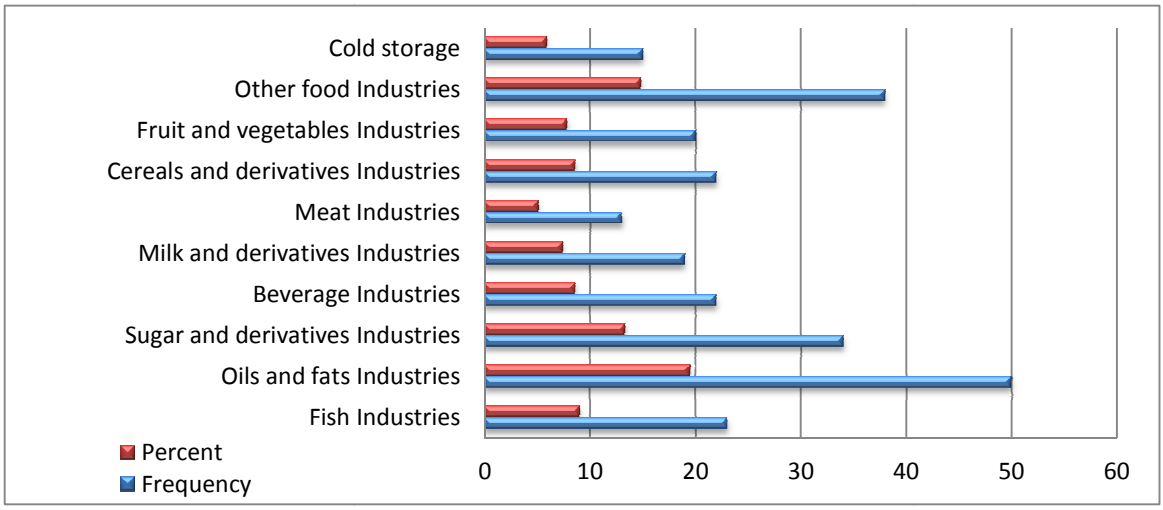

Fig 1 : The Industries of the companies visited

Most of the interviewed organizations are over 20 years old (28.5%). Our sample also shows a significant number of companies having an age of less than 5 years (23.4%) and an age between 5 and 10 years (24.6%). Choosing the companies according to industry promotion agencies and innovation was performed according to this variable. The preliminary assumption was that age has no effect on the identification of the variable.

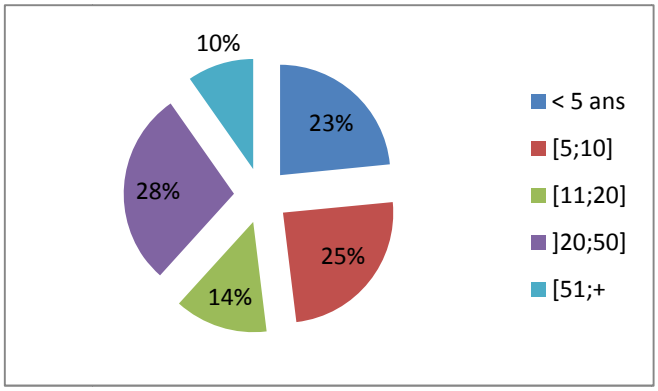

Fig2 : The age of the Tunisian agribusiness companies

Interviewed executives report that their organizations operate primarily at a continuous rate (32%) or fast (27%). Indeed, these organizations seek continuous improvement for the viability of their businesses. This sector is a flourishing one in Tunisia, employing 10 people or more. It also records the changes of activities, structures and technologies.

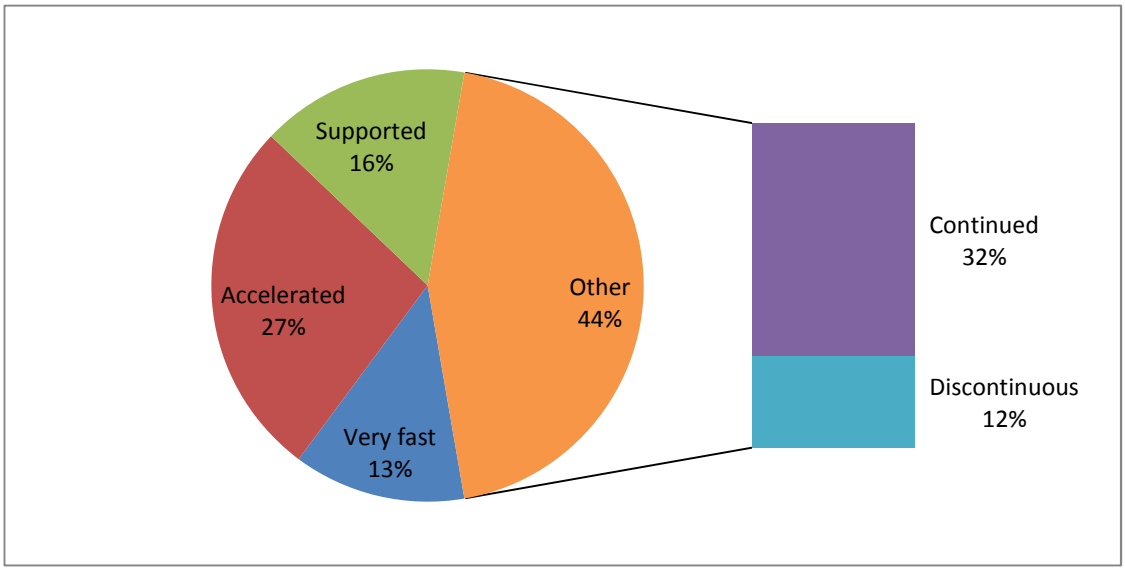

Fig 3: The rate of evolution of Tunisian organizations

Organizations are basically in the mature phase (43%). 32% are in the growth phase and 24.5% in visited the development stage. According to the perception of executives, their organizations go through three main phases. They opt for the continuity, stability and maintaining the market.

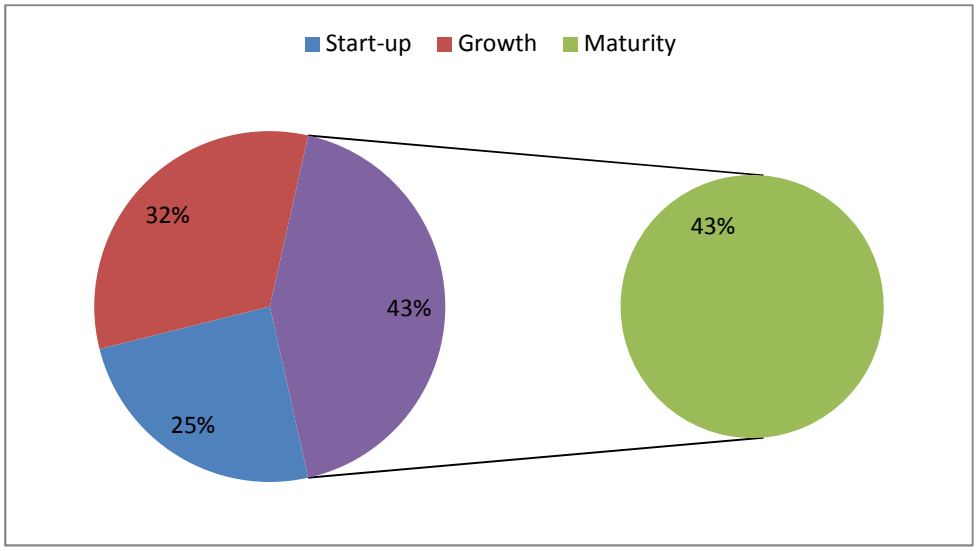

Fig 4 : The organizational life cycle phases of the Tunisian agribusiness

The Phases of the Tunisian Organizations

A factor analysis in main components of the life-cycle variables (depending on the scale of Lester and Parnell (2008)) was used to extract three factors (startup, growth and maturity). This echoes the work of Kazanjian and Drazin (1990). The scale is presented by fifteen items. The correlation of each item with the corresponding factor is satisfactory. Good reliability concerning each factor is very good. The Cronbach alpha coefficient ranges from 0.8 to 0.9. Internal consistency of each dimension is very satisfactory.

Most organizations are in the growth phase. Thus, leaders are struggling to identify their phases. Their perceptions are different from the criteria of evolution of their organizations. This is explained by their desire to develop while targeting maturity. Start-up organizations are described as simple. They are characterized by a fairly high degree of specialization. At the level of decision making, it is centralized. The level of complexity is relatively simple. This joined the work of Miller and Friesen (1984); Lester, Parnell and Carrahar (2003); Smith, Summer and Mitchell (1985); Hanks et al (1993); Saives et al (2005) and Silvola (2008) in the birth stage; Quin and Cameron (1983) in the entrepreneurial phase; Churchill and Lewis (1983) in the phase of the existence; Greiner (1977) in creativity by growth stage; Scott (1971) in its first phase.

Indeed, at birth organizations are characterized by a small formal structure, a unique production and control of personnel motivated by a paternalistic reward. The leadership uses a single person or what is called "One Man Show". Customers' research, product delivery and service delivery are the main concerns of the leaders. This is ensured by the simple structure with direct supervision. Planning is nonexistent. The main resources are the parents and friends. While the staff is destined for execution.

Organizations during the growth phase are characterized by product diversification, specialization with a slight differentiation. The information process ensures the watching out of the performance and facilitates communication between departments. Decision making is slightly decentralized and delegation is limited. The formalization of systems emerges but without management strengthening. At this stage, there is a specialization of functions and work (Greiner, 1977; Scott, 1971). After the development of resources, the leader promotes communication and formal structures at the growth phase (Quinn and Cameron, 1983). He has more confidence in his members (Lipppitt and Schmidt, 1967), which characterizes his delegation and the recourse to group decision-making. Members' commitment is valued and the level of work is intensified (Quinn and Cameron, 1983). However, the control is necessary to affirm the reputation and ensure the execution Greiner, 1977; Lippitt and Schmidt, 1967

Tunisian organizations in maturity are based on a functional structure, a sophisticated information processes, a participatory decision-making, bureaucratic formalization system and enhanced planning. Starting from this stage, the chief executive reports a slow increase compared to the growth phase. He intensifies the planning and control by a bureaucratic formalization and a by department functional structure (Lester, Parnell and Carrahar, 2003, Hans et al, 1993; Smith, Mitchell and Summer, 1985). Centralization is more moderate (Miller and Friesen, 1985; Hanks et al, 1993).

To classify Tunisian companies in the food industry according to their life-cycle phases, we provided a hierarchical typological analysis, and then we developed a non-hierarchical classification, according to the aggregation method of "Ward".
The observation of the homogeneity variance led us to identify three groups. We then checked the variance between group variance and inter group. Fischer's test is significant. To identify the groups, we performed a post hoc test (Duncan test). Each group is thus defined according to each phase. The phase distribution is almost equal.

The life-cycle of the Tunisian agribusiness organizations is tripolar. It is defined by three phases namely: Start, growth, maturity.

Conclusion

This research studies the life-cycle of Tunisian organizations belonging to the Tunisian agribusiness sector according to the twenty five items proposed in the model of Lester and Parnell (2008). Analysis of the results of our empirical research led to a life-cycle of the Tunisian agribusiness organizations defined by three phases.

This present study identifies the existence of a life-cycle of the organization like Kazanjian and Miles (1990) and specifies the phases according to the structure; specialization / differentiation; the information process; decision making and formalization.

Several potential research questions emerge. First, it is essential to refine and validate the new scale in order to defend the validity of the construction and the reliability of the measurement. Indeed, the scale developed in this study is no exception.

Similarly, the sector is not considered as a variable in this study. Thus, the influence of the food industry on .the life-cycle of the organization is not known.

Finally, this study classifies organizations on the basis of a response from a single company manager. A further study with the involvement of other members of the organization brings more clarification on the concept of the life cycle.

Key Enabling Technologies in Relation to Sustainable Development

Monika Dušková, Brno University of Technology, Faculty of Business and Management, Department of Economics, Kolejní 2906/4, 612 00 Brno, Czech Republic, duskova@fbm.vutbr.cz

Abstract

The article presents a review about the innovations especially in Key Enabling Technologies (KET), which are nowadays very popular and are closely related to the European Union strategy till year 2020. The KETs are regarded as the promising technologies regarding the sustainable development of Europe. Thus the sustainable innovations in companies particularly in Small and Medium Enterprises (SMEs) are discussed. The aim of the article is to present the KETs defined within the European Union policy for support its sustainable growth and development, and to compare the evaluation and development of KETs in recent years in European states. For this purpose, the qualitative and quantitative approaches were used for the evaluation of the KETs deployment on a European and global level. The implementation of KETs in Member States and others is also depicted.

Keywords: key enabling technologies, sustainable development, innovation, small and medium enterprices

Introduction

The sustainable development is a key modern issue in the 21st century, which is based on a maintaining of the quality life for present generation as well as for future one under the circumstances of the sources, technology and environmental limitation concerning the social issues. The very first time, the term sustainable development was adopted, was in 1969 by the International Union for Conservation of Nature (IUCN) (Adams, 2006), thereafter the term was spread and involved in many world forums, for example the United Nations Conference on Environment and Development held in Rio in 1992. This conference is considered as the milestone for the understanding and perceiving of the topic sustainable development for the whole scientific community. The modern definition of sustainable development, adopted by the conference as it is shown at the beginning of this paragraph, was taken over from the report Our Common Future of the World Commission on Environment and Development (WCED) in 1987 (Adams, 2006; Hirsch et al., 2006).

The governments, organisations and companies, which are highly aware of a necessity of the social and environmental issues solution, have adopted the principles of the sustainable development into their internal documents and strategies. The general public is also familiar with these issues, thus the organisations are forced to accepting and solving these topics in order to maintain the current customers, suppliers and partners and to attract the new ones. However, despite the partial successes the global concept of the sustainable development was still not established (Hirsch et al., 2006; Hedstrom et al., 1998; Holliday, 2001).

Theoretical Approach

Company sustainability

A huge amount of the studies and the scientific publications are dealing with the issue of the corporate sustainable development. All of them are equally based on the same concept of the three dimensions or pillars – economic pillar, which follows the economic activity, economic indicators and the aim of the

stakeholder value maximization; environmental and social pillars, which follow also the other aspects and benefits for the company as well as for the society. These main pillars are shown at the Fig. 1 (Adams, 2006; Hirsch et al., 2006; Hedstrom et al., 1998).

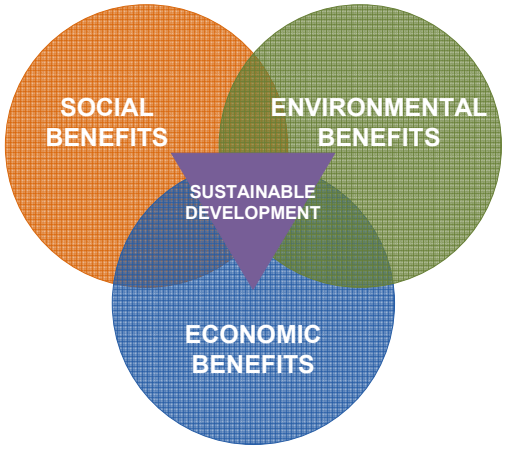

Fig 1. Three pillars of the corporate sustainability (Adams, 2006; Hirsch et al., 2006; Hedstrom et al., 1998).

Nowadays the companies are seeking the short-term goals and the positive economic indicators instead of the long-term vision and the heading of the company as a whole. The actual society focuses on the financial aspects on the business. The reason is that the economic indicators allow to evaluate the corporate management. On the other hand the trends that companies are aware of the environmental and social issues and consider them into their activities, begin to be more and more important.

The author Dyllick et al. (2002) agrees that not only a considering of the economic indicators for the company sustainable development are crucial, which he calls the economic capital, but also the natural capital, in a form of the natural sources, and social capital as a human resources are equally important. On this basis the author develops the corporate sustainability theory and defines the key features of these capitals referring to that each capital has its own importance. In a short-term point of view each capital can be followed separately, but in long-term the strong bonds exist between these capitals and they have to be addressed in relation.

The different perspective on the capitals is shown by the author Senge et al. (2001), who describes the next industrial revolution after that one in the 20th century – Industrial Era , which was typical by the exploitation of natural and human capital in order to gain the financial capital. The development patterns as they were set up in the Industrial Era and the huge consumption of the sources are no longer sustainable in the new era, which the author calls the New Economy. The author Senge et al. (2001) describes the corporate sustainability by the three dimensions: rationalism, naturalism and humanism. Up to now the rationalism, the belief in reason, has the dominant influence of the business and other corporate activities. Nevertheless, it has its limits, which can be solved by the approaches of the naturalism, in which the human is an inseparable part of the nature, and humanism, which involves the emotions, feelings, solidarity and the awareness that human is a part of society. The machine was the symbol of the industrial era, thus the nature should be the symbol of the new post-industrial era. According to it the new term biomimicry (Benyus, 1997) was established. It represents the innovation

motivated by the nature – for example there exist the "natural law" that the products in nature have no waste, which cannot be further processed by the nature itself. The author Senge et al. (2001) puts the questions, why this law should not be accepted as the other physical or chemical laws, why the society does not follow this law? The three possible strategies for companies are suggested (Senge et al., 2001; McDonough and Braungart, 1992; Holmberg and Robert, 2000).

- investments in the regenerative processes;
- renewable energy;
- waste reduction (resource productivity, clean production, remanufacturing, recycling and composting).

The authors discussed above agree on that the sustainable development is the challenge for the whole society, but the companies has the privileged position in this process due to their ability to initiate the significant conceptual and innovative changes.

Innovation and Sustainability

It is the subject of current public and private sector debates that the innovation (product, process, organizational or marketing innovation) are closely related to the sustainable development (Drucker, 2014; Vollenbroek, 2002). The modern companies face the increasing competition and dynamic changes of the markets due to many aspects such as globalization, e-communication, evolving new technologies etc. Thus it is crucial for companies as it has never been before, to include the innovation process into the company strategy and their activities in order to sustain the corporate development and gain the comparative advantage. It has been commonly assumed that innovation is the key driver for the economic growth (Guinet and Pilat, 1999; Bos-Brouwers, 2010; Abernathy and Clark, 1985). Besides the economic benefits, it brings the non-economic benefits as well (Larson, 2000). Those innovations, which provide with not only the positive economic results but also the environmental and social benefits, they are called the sustainable innovations (McElroy, 2003; Schaltegger and Wagner, 2011; Hansen et al., 2009). The integration of all aspects related to the sustainable development distinguishes the sustainable innovation from the standard one (Bos-Brouwers, 2010; Larson, 2000). The word "sustainability" is also often connected with many other specific fields such as production, manufacturing etc., which are all based on the definition of sustainable development and related three pillars system (OECD, 2009).

Other popular term related to the sustainable development and innovation, which is frequently and broadly discussed by many authors, is the eco-innovation (OECD, 2009; OECD, 2015; Fussler, 1996; Bossle et al., 2016). The author Fussler (1996) firstly used the term in relation to the new products and processes which bring the value to the company and its customers and lower the environmental impact at the same time. The OECD with its Innovation Strategy addressing the key societal and environmental challenges in modern world in relation to the eco-innovation, which stands for that the economic wealth goes hand in hand with environmental and social sustainability. This compound word represents the positive impact of innovation processes in companies on the corporate sustainable development. The concept of eco-innovation is broadly supported by many world governments, for example the European union implement the concept through the Europe 2020 strategy as the key to the future competitiveness (European Commission, 2011a) . The eco-innovation can be differentiated from the conventional innovation in two aspects. At first, it is much wider term than the standard innovation, and at second, eco-innovation is not limited to innovation of product, process, marketing or organisation, but also includes innovation in social issues and institutional structure (Rennings, 2000).

In any way it is called, the technological innovation as well as the non-technological are an important driver of the whole economic growth and they contribute to the world prosperity in societal and environmental aspects.

Role of Small and Medium Enterprises in innovation process

The small and medium-sized companies (SMEs) are those companies fulfilling the European requirements according to the Commission Recommendation (European Commission, 2003) presented in Tab. 1.

Table 1: The definition of small, medium-sized and micro companies *(European Commission, 2003)*.

Company category	Number of employees	Annual turnover	Balance sheet total
Medium	< 250	< 50 million EUR	< 43 million EUR
Small	< 50	< 10 million EUR	< 10 million EUR
Micro	< 10	< 2 million EUR	< 2 million EUR

The characteristic features of SMEs, which mean advantages or disadvantages in innovation process, in comparison to the large companies, are especially flexible organization capacities, strong regional focus on customer needs, horizontal management style with the dominant role of the owner, difficulty to attract finance. Due to the low degree of formalization, the decision making at lower management levels is supported and it allows the flexibility of SMEs. Because of the local market focus of SMEs, the entering into the innovation networks allows them to serve the international markets. This ability of SMEs to cooperate closely allow them also to share risks and gain access to other knowledge, services and technology. This all mentioned implicate that the SMEs innovate differently that the larger ones (Bos-Bouwers, 2010; Klewitz and Hansen, 2014).

The SMEs in relation to the innovation capacity and its implementation are studied by many authors, especially in comparison with the large companies (Van Dijk et al., 1997; Tether, 1998; Cohen and Klepper, 1996). Several authors conclude that the small companies can keep up with the large companies in the field of innovation based on the studies of the determinants that influence the innovation of companies in the mean of the research and development (R&D) intensity (Van Dijk et al., 1997). It was found out that the firm size, capital intensity (the barrier for new companies) and skilled labour determine the SME research and development and on the other hand the large companies R&D are affected only by the determinants profitability and market growth (Van Dijk et al., 1997; Tether, 1998).

Moreover, those studies of comparison between the innovation in SMEs and large companies based on innovation accounts examined that the SMEs presented more innovations per thousand employees than the larger companies (Tether, 1998). This is often interpreted like the SMEs are more efficient in innovation process or they are more innovative that large companies (Cohen and Klepper, 1996). However, this interpretation is based on the assumption that the value of innovations do not increase with the size of company on average. The author Tether (1998) explores the sensitivity of this assumption on the declaration about the SMEs innovation capacity in comparison to the large companies. If considering the average value of innovations increases with the size of company, the result is that large companies are more innovative.

Generally speaking, the SMEs are reckoned as an important player in the innovation processes and market competition especially in the field of the sustainable development (Larson, 2000; Schaltegger and Wagner, 2011; Hockerts and Wüstenhagen, 2010).

Key Enabling Technologies (KET)

Modern world is facing the societal challenges related to the sustainable development, such as climate change, poverty or resource and energy efficiency. To address these issues the European Union focuses at enhancing its innovative performance and bases the economy on knowledge and innovations. The EU defined six technologies as the promising crucial technologies to overcome the big challenges. These technologies are called the Key Enabling Technologies (KET) and they are the principal priorities of the European Union Strategy Europe 2020 and its flagship initiative of the Innovation Union aiming at the smart, sustainable and inclusive growth (European Commission, 2010).

KETs are knowledge associated with high R&D intensity, fast and effective innovation cycles, high-quality infrastructure and highly-skilled labour. They enable innovations in processes, goods and services within the whole economy and they are of significant relevance. They are multidisciplinary and cutting-across many technological areas. They are regarded as an important source for innovation. The KETs for European Union were identified on the basis of the global research and market trends and according to the studies of different countries such as China, Japan or the USA and also European countries such as Germany, United Kingdom or France (European Commission, 2009a; European Commission, 2009b). There were determined the several technologies with the strategic importance for the economic sustainable growth, addressing the societal challenges and creating a huge knowledge base that would help the Europe stepping-up and enabling the European companies to compete on a global market (European Commission, 2009a; European Commission, 2009b; European Commission, 2012a):

- **Nanotechnology**
  It is a huge field covering the design, structure, characterization, analysis or products at nano-scale resulting into the products for healthcare, manufacturing etc.
- **Micro and nano-electronics**
  This field is related to the semiconductor components and miniaturised electronic systems in larger final products that are used in many industrial sectors for intelligent control.
- **Photonics**
  Photonics deals with the light generation, propagation and detection. Typically it involves the conversion of sunlight to electricity and also the solar cells, LED technology etc.
- **Advanced materials**
  The advanced materials in the meaning of the low-cost substitute to existing materials and also the new high value added materials in order to decrease the environmental impact of these materials and resource consumption.
- **Industrial biotechnology**
  The application of biotechnology for industrial sectors such as the production of chemicals, materials or fuels. It includes the using of microorganisms or their components (enzymes) to product industrially useful results.
- **Advanced manufacturing systems (technologies)**
  The wide range of high-tech procedures and processes for manufacturing, leading to improvements in terms of new product properties, production processes or cost, energy consumption etc.

Because of the KETs importance for the EU policy, there were determined several programmes which support the KETs implementation on international and national level. There exists the huge programme Horizon 2020, which aims at financial and non-financial support of the R&D activities and innovations in all Member states. Within this programme there are many sub-programmes and initiatives that aims at specific topics, applicants etc. On the national level the European Structural and Investment Funds implements the cohesion policy of EU in order to reduce the differences between the economic levels of Member states. KETs technology are significantly promoted via these tools and they often aim at SMEs

(European Commission, 2012). In 2014 The European Commission launched a new initiative aiming to support innovation in SMEs through the identification of the existing KETs Technology Infrastructures across Europe to enhance their collaboration and to enable an access of SMEs to the services offered by the platforms and to evolve the innovative ideas in KETs (European Commission, 2016a). The KETs infrastructure is shown at Fig. 2.

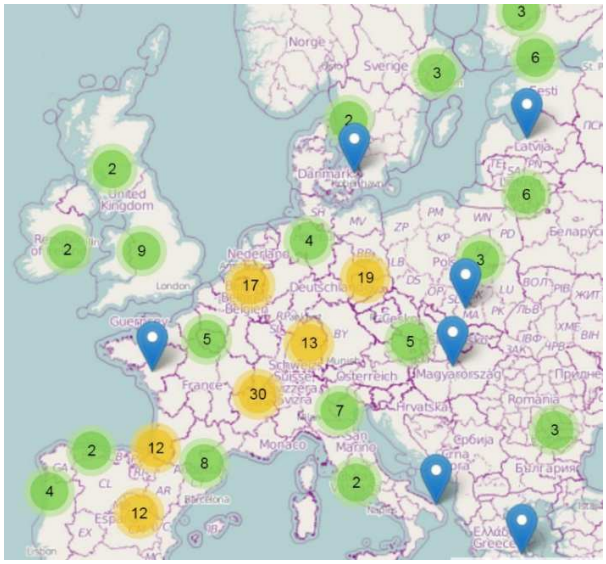

Fig 2. The map of the KETs infrastructure for SMEs (European Commission, 2016).

Methodology

The KETs are technologies, which are multidisciplinary thus their evaluation is complicated by the fact, that there are not specified the fields, which belong to each KET. Nevertheless, several extensive studies based on different quantitative analyses were presented and various types of methodology for the evaluation was set up. The qualitative evaluation of the KETs development is monitored by the groups of experts in each KET.

Qualitative assessment of KETs deployment

To assess and support the progress of implementing the strategy for KETs on the European level there exists the High-Level Group (HLG) comprising the industrial representatives, technology providers for each KET, industrial users, representatives of research community and financial sector and others who are connected with KET on different levels from the European Members states. The aim of HLG is to elaborate and develop the coherent European strategy for KETs (European Commission, 2011b).

The First High-Level Group was established by the European Commission in 2010 and one year after the Final Report was published (European Commission, 2011b). The purpose of the First HLG was to participate in a creation of the EU strategy encompassing KETs.

The Second HLG, which were established in 2013, published the Implementation Report in the same year (European Commission, 2013). This documents presented the discussion about the KETs policy of EU, the implementation plan for KETs and the promotion to the Member states. The HLG studied the KETs

in a global aspects, which were then compared with the European level and, as a result, the recommendations were formulated.

In 2015 there was published the Final Report of the Second HLG with recommendations, how to enhance the KETs within the European Union (European Commission, 2014). One of the recommendation of the HLG is the necessity of investments in KETs based manufacturing to sustain economic growth and boost competitiveness and job creation. The Europe should base its development on the high-quality research capability aware of being catching up with the USA and Asian states. The European Union should focus on the bridging the gap between the research and technology implementation into industry.

Quantitative evaluation of KETs deployment

The quantitative evaluation of the KETs implementation and development in European Union is the subject of several studies especially those, which aims at documenting the EU strategy and policy progress. Thus, many studies for the purpose of European Commission were prepared. Because of the complexity of the KETs, there must be set a system of indicators, which can assess the KETs development in countries. They are based on the analyses of the patent performance, production, market share or export and import.

The European states were evaluated in the study Exchange of good policy practices promoting the industrial uptake and deployment of Key Enabling Technologies from the year 2012 (European Commission, 2012b). The country performance in KETs was measured by a set of performance indicators, which were based on patent (data from PATSTAT European Patent Office EPO Worldwide Patent Statistical Database) and trade activities (United Nations Commodity Trade Statistics) in each country. Each indicator was defined by the several minor indicators (significance, market share, specialization, dynamics). As a result the composite indicators were calculated from the performance indicators. Then based on the Free Disposal Hull analysis (De Borger et al., 1994) the data were plotted, where the so called “production frontiers” can be determined. This analysis enabled to define the lessons learned and some recommendations.

Comparison of the KET deployment of EU and other states presents the study Production and trade in KETs-based products: The EU position in global value chains and specialization patterns within the EU from the year 2013 (Velde, 2013). The analysis is based on the indicators such as market share, comparative advantage, trade surplus and export and import and it displays the EU position in international trade and in value chains (in the meaning of a technology content). The competitiveness was evaluated by the production of new technologies via patents (using the database PATSTAT). To identify the position that Europe holds in global value chains within each KET, the trade indicators (similar to the previous one) were used.

At last but not least, because of the importance of the KETs for the European Union and its sustainable development, the analytical tool KETs Observatory was established by the European Commission (European Commission, 2016b). The KETs Observatory follows two complementary approaches to evaluate the performance of KETs at different stages of the whole value chain. The evaluation consists of several concepts and indicators (European Commission, 2015; European Commission, 2012c):

- technology generation and exploitation approach – the ability to transfer new ideas and knowledge into innovations is measured by:
- technology indicators – patents, which are closely related to the industrial applications (using International Patent Classification IPC/WIPO)
- production indicators – production dynamics of the KETs based components (using Community Production PRODCOM)

- turnover indicators – the ability of companies to compete at KETs relevant markets (using HS codes by World Custom Organization)
- composite indicators - the ability of countries to cover the KETs deployment value chain from technology development to commercialisation (using IPC and NACE)
- technology diffusion approach – to show what EU is using the potential of KETs to improve its competitiveness and application on KETs, which is measured by:
- employment indicators – value creation of KETs in various industries (using PRODCOM)
- production and demand indicators – the potential of KETs to improve its competitiveness by manufacturing KETs based products and their application (using PRODCOM and NACE)

The KETs Observatory is the online tool, where there are presented actual information about the EU performance in KETs for each Member State which are based on the calculation of the indicators named above (European Commission, 2016b).

Results and Discussion

The result of the study by European Commission (2012b) from the year 2012 are presented in Tab. 2. The study calculate the trade and patent performance. The patent performance was determined for the period 2005-2008 and the trade performance for 2000-2010. According to these criteria the countries that show a quite excellent combination of patent and trade performance were identified. Then the high performance level of those countries in KETs was defined as follows:

- Frontier – "production frontier" in patent and also trade performance
- High – below the production frontier level, but strong patent performance
- Medium - close the production frontier level, but medium or low patent performance
- Low – production frontier or close to it, but no or almost no patent performance.

Table 2: Overview of performance profile per country and KET (European Commission, 2012b).

		Photonics	Nanotechnology	Biotechnology	Advanced materials	Electronics	Manufacturing
AT	**Austria**	-	-	-	-	Medium	Medium
BE	**Belgium**	-	Frontier	Frontier	Frontier	-	-

UK	**United Kingdom**	Frontier	High	Medium	-	Medium	-
CN	**China**	Frontier	High	Medium	High	High	High
IL	**Israel**	Medium	Medium	Medium	-	Frontier	-
IN	**India**	-	High	Frontier	High	-	-
JP	**Japan**	High	High	High	High	Frontier	High
KR	**South Korea**	Frontier	High	Medium	Frontier	High	High
US	**USA**	Frontier	Frontier	High	High	Frontier	High

From the Tab. 2 it is obvious, that for some countries the data for all KETs were not at disposal. Many European countries shows a great results (frontier) in at least one KET. Germany, Poland, Belgium and Bulgaria are the frontiers or at high level performance in several KETs. From the global point of view India, Japan and USA are also the frontiers or high level performance countries. One of the suggestion according to these results is that countries on the level “Frontier” or “High” should be supported within next years by huge investments in further development of the KET (European Commission, 2012b).

The comprehensive study by Velde et al. (2013) from the year 2013 is focused at the quantitative and also qualitative analysis of each KETs and their key sub-topics and relevant industrial fields. It consists of the extensive description of modern trends in KETs. Also the technology market shares based on the data from PATSTAT were calculated. When calculating market shares based on international patents number, it should be bear in mind that some limitations of patent count data can occurred. Not all new knowledge is represented by patents and on the other hand some patents have never been used for innovations. Also the economic added value, which is represented by one patent, is variable. At last, other purpose of some patents is to block the competitors in developing new technologies. There is a general agreement in technology research, however, that patent data accurately represents the main structures and development of technology markets. Moreover, using of international patent applications are expected to have a higher commercial value in comparison to the national patents, which are usually cheaper and with a lower expected commercial value (Velde et al., 2013).

The results presented in the study by Velde et al. (2013) are comparing the market share for all patents and KETs patents in total and for each KETs for the period 2000-2010. From the global point of view the declining trend is obvious for Europe, North America and the rest of World excluding Asia. Only East Asia increased its market share during this period of time in all technologies and KETs as well. In four of the KETs (photonics, advanced materials, micro-/nanoelectronics, advanced manufacturing) the East Asia plays the most significant role. In the rest two ones, the key player is North America. Other results from the study by Velde et al. (2013) are reported in Tab. 3.

Table 3: Market shares in international patents in the KET fields in 2000-2010 for European States in % (Velde et al., 2013)

		Photonics	Nanotechnology	Biotechnology	Adv. materials	Electronics	Manufacturing
AT	**Austria**	increase 2% -> 5%	-	-	-	-	-
BE	**Belgium**	-	-	-	vary about 4%	-	-
DE	**Germany**	increase 39% -> 42%	decrease 41% -> 24%	decrease 45% -> 30%	decrease 47% -> 41%	decrease 50% -> 45%	decrease 46% -> 38%
DK	**Denmark**	-	-	vary about 5%	-	-	-
FR	**France**	vary about 12%	increase 14% -> 24%	increase 10% -> 14%	increase 14% -> 15%	increase 10% -> 15%	increase 13% -> 15%
CH	**Switzerland**	-	decrease 7% -> 4%	vary about 7%	increase 3% -> 5%	vary about 5%	vary about 6%
IT	**Italy**	vary about 5%	vary about 5%	-	vary about 6%	vary about 4%	-
NL	**Netherlands**	vary about 13%	vary about 10%	vary about 10%	-	decrease 15% -> 7%	decrease 9% -> 7%
SE	**Sweden**	-	decrease 7% -> 4%	-	-	-	vary about 4%
UK	**United Kingdom**	decrease 14% -> 8%	-	decrease 15% -> 10%	vary about 6%	vary about 6%	decrease 9% -> 7%

In Europe, Germany is the main producer of KET patents in the period 2000-2010 in each of the six KETs, but during the time its importance is decreasing. France increased its market share in five KETs or at least maintain the value in photonics. In general, the other states are maintaining their market shares during the time period, some of them strengthened their position (Austria and Germany in photonics and Switzerland in advanced materials). The decrease in range 2-8% (excluding Germany, where the decrease is much higher) can be seen in United Kingdom in photonics, advanced materials and manufacturing, Switzerland and Sweden in nanotechnology, Netherlands in micro and nano electronics and advanced manufacturing.

The stagnation or decreasing trends illustrate quite disappointing situation in Europe. Moreover some particular fields within the KETs are more ambitious and perspective and they are expecting to increase their market share (the detailed description of the sub-fields is in the study by Velde et al. (2013)).

Table 4: Country ranking in composite analysis for all KETs (PHOT – photonics, NT – nanotechnology, IB – industrial biotechnology, AM – advanced materials, MNE – micro and nano electronics, AMT – advanced manufacturing technologies) (European Commission, 2015; European Commission, 2012c).

		PRODUCTION						TRADE						TECHNOLOGY

The Tab. 4 summarizes the newest results of technology generation and exploitation evaluation approach based on the production, trade and technology indicators of the study from 2015 (European Commission, 2015) and the results from the KETs observatory tool (European Commission, 2016b; European Commission, 2012c). The numbers in table represent the ranking of the country in each KET (the lowest number the better). For clear interpretation, the colour differentiation were used: green for results in range

1-10, grey for 11-20 and red for 21-28. The data used for the indicator calculation are from the time period 2003-2013.

In comparison to previous studies, the data reveals the very strong position of the United Kingdom in all KETs and within all indicators. Also Germany, Austria, Netherlands, France, Italy and Belgium confirmed their strong position in compliance with the other studies. Moreover, some other countries present satisfactory results in this study, for example Czech Republic, Denmark, Hungary, Ireland, Poland and Nordic countries Sweden and Finland. The explanation for it could be that the newest data (for period 2011-2013) were included and newly mentioned countries increased their activities during that period.

Conclusion

The article dealt with the Key Enabling Technologies regarding to their importance for the sustainable development of mainly the European countries. Also the KETs in relevance to the sustainable innovations especially for the SMEs were discussed. The concise literature review about KETs and its evaluation were presented. Finally the different approaches for KETs evaluation were briefly described and the results of these approaches were presented and compared.

The KETs are a crucial issue of the European strategy for sustainable development since 2009 (European Commission, 2010; European Commission, 2009b). They define several research fields, which are considered as a promising and highly potential fields for production of applicable results into industry and society. These modern fields are crossing the disciplines in order to come up with novel approaches how to deal with the sustainability of economies as well as the companies. They will also solve the environmental issues and social problems. European and national financial resources for supporting the projects of research and development aim at boosting KETs within Europe.

Despite the importance of KETs for European Union, only a few studies, which were focused only at the KETs deployment, development and their evaluation were published. These results were summarized and concisely presented.

During the time period 2000-2013, for which the data were calculated, the results show up the key players in KETs in general, such as Germany, France, United Kingdom, Netherlands or Austria. Also some KETs, especially nanotechnology and advanced materials, have a higher importance within the European Union, because several states achieve good results in these fields in global comparison.

The indicators and the calculation process of KETs development as well as the quantitative implementation of KETs in accordance with SMEs were not the subject of the article, but it will be the subject of further research. Moreover the multidisciplinary character of KETs should be considered within the calculation process of indicators.

Acknowledgment

The research is financed by Internal Grant Agency of the Brno University of Technology. Name of the Project: Economic Determinants of Competitiveness of Enterprises in Central and Eastern Europe. Project Registration No. FP-S-15-2825.

Using Value Added in Sustainability Measurement

Ing. Markéta Součková, Brno University of Technology, Faculty of Business and Management, Department of Economics, Brno, Czech Republic, souckova@fbm.vutbr.cz

Abstract

Purpose of the article: Managers use EVA (economic value added) technique for measuring of value creation. This article provides explanation of EVA, how to measure EVA, value added and how it is used by companies. And finally, it provides an explanation of EVAS (Expanded value added statement). EVAS applies social and environmental aspects. These aspects are important over time. It helps companies to account for sustainabilty. This article also provides explanation three pillars of sustainability. Methodology/methods: Compare EVA and value added in industry sectors in the Czech Republic. Numbers are obtained in statements. Findings: Companies in the Czech Republic use EVA equity. Compare value added and disposal value among the stakeholders. Conclusions: Value added is mostly lower than disposal value among the stakeholders.

Keywords: EVA, economic value added, value added, EVA equity

Introduction

The Economic Value Added is used for measuring of value creation. Eva is a trademark of Stern Stewart & Company. Popularity of EVA is increasing. Managers realize the importance of added value and sustainability. There were two historic reasons to start using EVA as a measure of value. Both happened around 1980s. Traditional accounting methods generated unsuitable measurements of company performance and Japanese companies started to compete with American companies. Sustainability became more important. A lot of authors since tried to express value added and sustainability. The core ideas are EVAS or Sustainable value added. Sustainability is a concept from Brundtland Report from 1987.

Theoretical Approach

Alfred Marshall, the noted Cambridge economist, developed the related concept of economic income more than 100 years ago. Young, (1997) acording this concept a company earns genuine profits only when revenues are sufficient to cover the firm's operating costs and its cost of capital.
Stern, (1995) and Stewart (1991), EVA is a trademark of Stern Stewart and Company consultant group Bahri, St-Pierre, & Sakka (2011) it is a technique for the measurement of value creation and measurement the wealth a firm creats in a given period. Young (1997) zi tells to investors and managers where value has been created in the business and where value has been destroyed. It measures a company's success in creating shareholder value. EVA measures the difference between the return on a company's capital and the cost of that capital.

Rappaport (1999) said that EVA can be defined as the firm operating profit after taxes (NOPAT), less the cost of capital

Reasons to use EVA

Kaplan (1983) EVA started to use because of two important trends.

- During the 1980s it became clear that traditional accounting methods often generated very unsuitable measures of firm performance. This is e.g. FIFO vs. LIFO, depreciation methodology etc., and this is important in the analysis of profitability.
- Tortella (2003) During the 1980s Japanese firms started to compete american firms and, at the same time, financial markets internationalized and experienced a huge expansion.

Young (1997) EVA is innovative in three important ways.

- EVA isn´t bound by GAAP. EVA counts the cost of all capital, and it is not limited by generally accepted accounting principles. The net income numbers, which are in statements of income consider only the most visible type of capital cost, interest, and ignoring the cost of equity finance. It s possible to understad of EVA that it represents a company's profits net of the cost of both debt and equity capital.
- EVA proponents have been pushing firms to use EVA in successively lower levels of the organization, on the assumption that all employees, not only senior managers, must undertake their tasks with the overriding goal of creating shareholder value.
- EVA offers measuring and communicating performance that can be used in the capital markets, for capital investment appraisal, and in the evaluation and compensation of managerial performance.

EVA measurement

Abate (2004):

$$EVA = NOPAT - WACC * C$$

Where:

NOPAT: Net Operating Profits After Taxes.
WACC: Weighted Average Cost of Capital.
C: value of total capital invested

Acording Prober (2000) and Rappaport (1999). The information required to calculate EVA is obtained mainly from accounting data. But the information from accounting has to go through some adjustments, for example: some of these adjustments are to add back deferred tax reserves and bad debt reserves, goodwill amortization, and LIFO reserve increase. Acording Wallace (1997) the EVA methodology uses modifications of GAAP earnings in addition to a capital charge Tortella (2003).

In narrow sense EVA can be calculated by this formula:

$$EVA = (ROE - r_e) * E$$

Where:
ROE: return on equity
r_e: market cost of equity
E: equity

Dluhošová (2004) this EVA is used in the Czech Republic. The authors are Inka and Ivan Neumaier. It is important for the owners the (ROE- re) spread to be as large as possible or at least positive. Only in this case investment to the firm brings more than an alternative investment.

Sustainability

The principal inspiration of sustainability came from the Brundtland Report of 1987.
The term gained widespread usage after 1987, when the Brundtland Report from the United Nations' World Commission on Environment and Development defined sustainable development as development that *"meets the needs of the present generation without compromising the ability of future generations to meet their own needs."*

The essence of the term sustainable is "*that which can be maintained over time."* In the 1980s, Swedish oncologist Dr. Karl-Henrik Robèrt brought together leading scientists to develop a consensus on requirements for a sustainable society. In 1989 Dr. Karl_Henrik Robèrt formulated this consensus in four

system conditions for sustainability. These conditions became the basis for an organization, the Natural Step. The four conditions are:

In a sustainable society, nature is not subject to systematically increasing:
1. concentrations of substances extracted from the earth's crust.
2. concentrations of substances produced by society.
3. degradation by physical means.

And, in that society:
4. people are not subject to conditions that systematically undermine their capacity to meet their needs. Heinberg (2010) there have been two major developments in the concept of sustainability:

- there are three dimensions, which must be in harmony: social, economic and environmental
- 'strong' and 'weak' sustainability

Three pillars of sustainability

Three pillars of sustainability consist economic aspects, environmental aspects and sociological aspects.

- Economic - is the ability of an economy to support a defined level of economic production indefinitely.
- Envrionmental- is the ability of the environment to support a defined level of environmental quality and natural resource extraction rates indefinitely.
- Social - is the ability of a social system, such as a country, family, or organization, to function at a defined level of social well being and harmony indefinitely.

Agyekum (2012) the basic necessities of human existence are food, clothing and shelter. For example, shelter associated with the built environment. Sustainability buildings are independent, save energy, produce little waste.

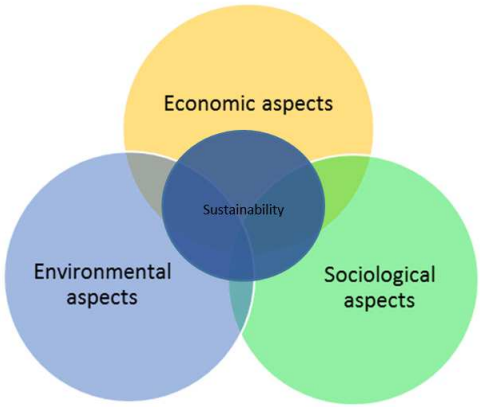

Fig. 1: Three pillars of sustainability

Weak and strong sustainability

Daly (1997) sustainability is what resources we bequeath to coming generations: natural resources, quality of the environment, and capital. Some loss of natural resources is inevitable, but this may be compensated for by increased capital (Robert Solow) Others say, that sustainability is a matter of preserving natural resources essential for our survival. Pearce (1992) defined this two views as „weak" and „strong" sustainability: et al:

- *„That the next generation should inherit a stock of wealth, comprising man-made assets and environmental assets, no less than the stock inherited by the previous generation;"*
- *„That the next generation should inherit a stock of environmental assets no less than the stock inherited by the previous generation."*

Kuhlman (2010) some resources must fall under the requirement of strong sustainability, others under the weak variety. It depend on the degree to which they can be substituted by capital.

Pearce et al., (1989) the question of different kinds of capital can be represente by one another is directed by the concepts of weak and strong sustainability. Pearce and Atkinson (1993). Weak sustainability implies that all forms of capital are substitutable by each other so that any loss in one kind of capital can in theory be substituted by a surplus in other forms of capital.

Figge (2004) one way of assessing corporate contributions to sustainability is to subtract the costs from the benefits created by a company. For this purpose both internal and external costs need to be considered. They can be derived from full cost. Following this approach, a company contributes to sustainability, if the benefits exceed the sum of internal and external costs. The result can be called 'net value added'

Heinberg (2010) formulated five axioms (self-evident truths) of sustainability.

- Any society that continues to use critical resources unsustainably will collapse.
- Population growth and/or growth in the rates of consumption of resources cannot be sustained.10
- To be sustainable, the use of renewable resources must proceed at a rate that is less than or equal to the rate of natural replenishment.
- To be sustainable, the use of nonrenewable resources must proceed at a rate that is declining, and the rate of decline must be greater than or equal to the rate of depletion.
- Sustainability requires that substances introduced into the environment from human activities be minimized and rendered harmless to biosphere functions.

Metodology

EVAS

Acording Mook (2007) the Expanded Value added Statement (EVAS) deal with some of the difficulties in applying accounting models developed for business enterprises to non-profit organizations. Non-profit organizations are different from business enterprises. Non-profit organizations don t operate to earn a profit only. Non-profit organizations accept the contribution of multiple stakeholders (funders, clients, and community) and involve volunteers.

The EVAS doesn´t concentrate only on financial surpluses or deficits. It concentrates on economic and social impacts too. The EVAS also emphasizes the collective effort needed for an organization to achieve its goals, viewing each stakeholder as important to its viability as a socially and economically responsible organization. For example, including volunteers and society as stakeholders presents an alternative perspective of an organization to focusing solely on its ability to spend its financial resources. Thus, the EVAS includes non-monetized social contributions of volunteers who become one of the stakeholders; a portion of the value added is distributed to them. By combining financial and social value added, the EVAS also emphasizes the interconnectedness and interdependence of the economy, community and environment. Overall, every EVAS contain two parts: the calculation of value added by an organization and its distribution to the stakeholders.

Ruggles & Ruggles (1965) EVAS is based on a traditional accounting statement but modified to include social and environmental items. The question is what is value added? Value added is measured by the difference between the market value of the goods or services produced, and the cost of goods and services

purchased from other producers. Riahi-Belkaoui (1992) the left side shows the value added and the other side shows the disposal value among the stakeholders. In equation is:

S-B=W+I+DP+D+T+R

Where S=Sales revenue
B=Bought-in materials and services
W=Wages and benefits
I=Interest
DP=Depreciation
D=Dividends
T=Taxes
R=Retained earnings

Mook (2007) the EVAS is not intended to replace existing financial statements, but to supplement them. By synthesizing traditional financial data with social and environmental data, the EVAS provides additional valuable information for understanding the dynamics of an organization and one that shows great potential by focusing attention on value creation and use.

Table. 1: EVAS – Sustainable Building Co. (USD)

EVAS		F1	F2	FTTL	SOCENV1 (Benefits for customers)	SOCENV2 (Benefits for society)	CTTL
Direct outputs	sales	5,250,000	106,050	5,356,050			5,356,050
Indirect outputs	Energy value				101,325		101,325
	Water value				8,925		8,925
	Other operating costs				148,225		148,225
	Productivity and health value				645,575		645,575
	Waste value					525	525
	Emissions value					20,650	20,650
Total outputs				5,356,050	904,050	21,175	6,281,275
Production consumption		3,600,000	100,000	3,700,000			3,700,000
Value added created by the company		1,650,000	6,050	1,656,050	904,050	21,175	2,581,275
Ratio of value added to production consumption		0.46		0.45	0.24	0.01	0.70
Employees	Wages/benefits	1,250,000		1,250,000			1,250,000
Customers					904,050		904,050
Society	Reduction in wastes and emissions					21,175	21,175
	Taxes	50,000	1,000	51,000			51,000
Company	Depreciation	100,000		100,000			100,000
	Profit	250, 000	5,050	255,050			255,050
Distribution of value added		1,650,000	6,050	1,656,050	904,050	21,175	2,581,275

Source: Mook, L.: Integrating and Reporting an Organisation's Economic, Social and Environmental Performance, The Expanded Value Added Statement, in: Schaltegger, S., Bennett, M. and Burritt, R. (Eds.): Sustainability Accounting and Reporting. Dordrecht: Springer, 281-298, 2006.

Mook (2007) the first thing you need to do is to calculate value added. Determination of total business output and comparison with other products on the market. In the above example the direct outputs include proceeds from the sale of buildings that were built using traditional construction methods. These direct outputs are listed in the column F1. In column F2 are then additional revenues, which are derived from so-called. "Sustainable" buildings, and should cover the direct output value of the company for the period. Column headed SOCENV1 and SOCENV2 are indirect outputs, which in this example represents a savings of "sustainable" buildings for customers and society. We can mention for example: saving water, energy, building repairs etc.). Also in the column F1 and F2 is recognized the cost of the consumed material, services, energy, etc. It is apparent that "sustainable" buildings increase the value of material purchased, services and energy. EVAS provides information about the added value not only for employees or enterprise, etc., but also for customers and the society.

While compiling the EVAS report it necessary to take into account the limitations of this statement. It is necessary to choose what items will become part of the statement and to choose the method of valuation for each item. It is also associated with identifying and quantifying the value of key environmental and social factors, which reflect the degree of sustainable performance. The statement is linking economic performance, environmental performance and social performance and shows the relationships between them.

This is example of EVAS in building industry. Of course it can be aplicated on different kinds of industry too. It s possible to do another statement.

Result and Discusion

This part is about EVA index development in Czech Republic within the industry area. In Czech Republic, EVA is being measured based on economic profit:

$$EVA = (ROE - r_e) * E$$

The following table and graph shows EVA development in selected sectors of manufacturing industry in Czech Republic during years 2012-2014.

Table. 2: EVA development in selected sectors of processing industry (mil. CZK)

Industry	2012	2013	2014
Manufacture of basic pharmaceutical products and pharmaceutical preparations	108 826	-472 999	807 900
Manufacture of machinery and equipment	-1 366 644	2 155 997	3 183 402
Manufacture of wood and of products of wood and cork, straw and plaiting materials, except furniture	-686 852	-522 363	-125 026

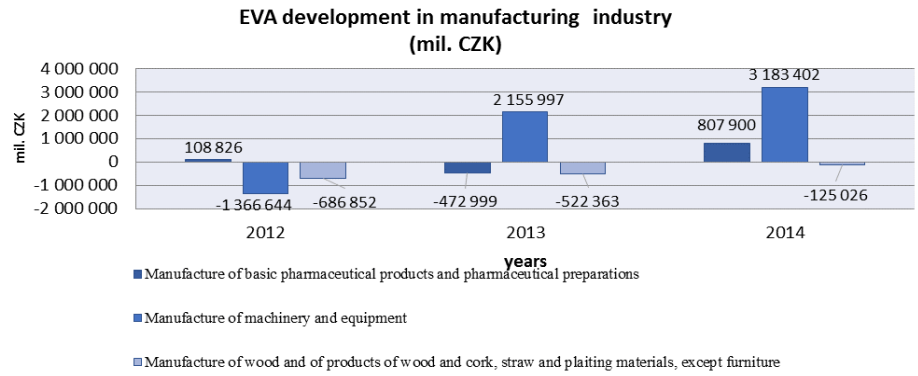

Fig. 2: EVA development in selected sectors of processing industry (mil. CZK)

In some sectors of manufacturing industry EVA is positive and growing. In particular, the manufacture of machinery and equipment. Conversely, in the wood processing EVA is negative, even though the value is getting closer to positive numbers. It has a growing trend. Pharmaceutical production has an fluctuating EVA indicator. EVA is positive during 2012, negative for the following year 2013 and then again rising and positive in the year 2014. These data are available at the Ministry of Industry and Trade of the Czech Republic.

The largest increase of the indicator can observed within manufacturing of machinery and equipment, where from the initial value of -1,366,644 million CZK the value jumps high into positive numbers, specifically to the amount of 2,155,997 million CZK. The smallest fluctuations of the indicator are present within woodworking.

Table 3: Selected kind of construction industry (mil. CZK)

Industry	2012	2013	2014
Building	-1 175 253	-886 343	-2 151 717
Civil engineering	8 599	-1 670 437	-164 985

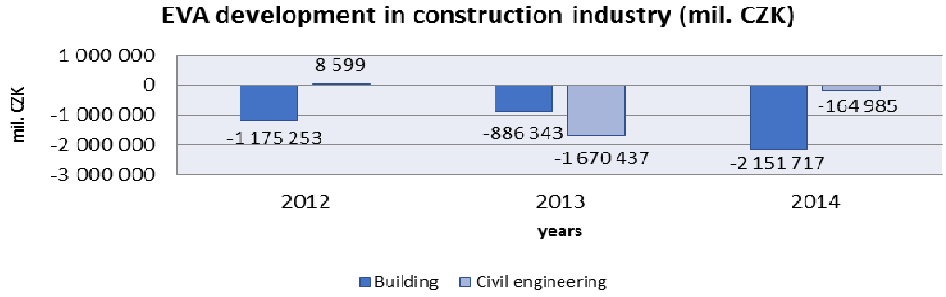

Figure 3: EVA development in construction industry (mil. CZK)

Two areas are being compared within the construction industry. It is the construction of buildings and civil engineering. The latter had a positive EVA value in 2012, but it turns negative during the following

years. The area of building construction is negative long-term. It even reaches the value of -2,151,717 million CZK.

The table lists these values for company Žďas, Inc. which is working within the engineering industry and for the company PSJ, Inc., working within the construction industry. The data are in millions of Czech crowns and available as a part of the annual accounting reports.

Table 4: Accounting data (thousand CZK)

Benchmark	Year	Žďas, Inc. (engineering)	PSJ, Inc. (construction)	Benchmark	Year	Žďas, Inc. (engineering)	PSJ, Inc.. (construction)
S	2012	3 321 810	6 442 675	DP	2012	176 318	18 921
	2013	2 973 444	3 987 138		2013	188 700	19 385
	2014	3 057 283	5 498 362		2014	197 111	20 571
B	2012	2 039 715	6 034 953	D	2012	70 000	78 311
	2013	1 760 881	3 670 406		2013	250 000	61 850
	2014	1 836 910	4 941 201		2014	138 000	65 674
W	2012	949 962	253 914	T	2012	21 514	3 259
	2013	956 755	224 369		2013	18 690	29 335
	2014	948 792	230 351		2014	20 012	32 576
I	2012	4 286	25 740	R	2012	88 722	116 629
	2013	5 028	50 311		2013	72 228	101 934
	2014	5 487	43 769		2014	65 197	131 349

The following table contains Gross Value Added and disposal value generated by the enterprises. In both companies, the Gross Value Added and disposal value among the stakeholders is positive across all measured years.

Table 5: Gross value added and disposal value (thousand CZK)

Company	S-B			W+I+DP+D+T+R		
	2012	2013	2014	2012	2013	2014
Žďas, Inc.	1 282 095	1 212 563	1 220 373	1 310 802	1 491 401	1 374 599
PSJ, Inc.	407 722	316 732	557 161	496 774	487 184	524 290

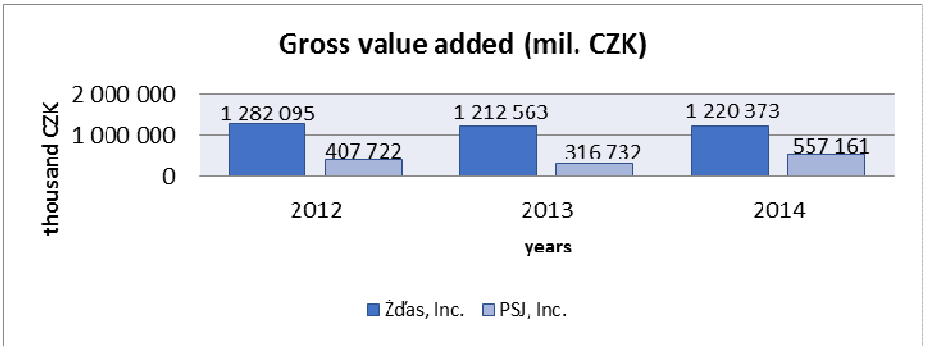

Figure 4: Gross Value Added (thousand CZK)

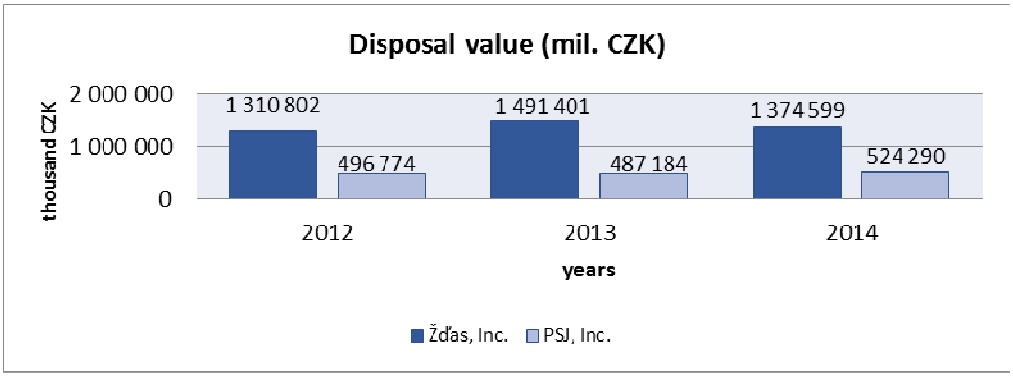

Figure 5: Disposal value (thousand CZK)

The highest positive GVA can be observed for the company Žďas, Inc. during year 2012. In subsequent years, an decrease is apparent for this value. For the construction company PSJ, Inc.,the value decreases in 2013 and next year the value is the highest. The highest disposal value among the stakeholders can be observed for the company Žďas, Inc. during year 2013. For the construction company PSJ, Inc. is disposal value among the stakeholders has the same trend as GVA. The highest sales of Žďas, Inc. were around 3 321 810 thousand CZK in 2012. The highest sales of PSJ, Inc. were around 6 442 675 thousand CZK in 2012. The highest bought materials and services were in 2012 for both companies. Žďas, Inc. Had the highest dividends 250 000 thousand CZK in 2013. But another company had dividends 78 311 thousand CZK in 2012. The highest retained earnings had PSJ, Inc. in 2014.

Conclusion

This paper has focused on using EVA and especially in the Czech Republic during years 2012-2014. In other countries reported to be use EVA, which is determined Net Operating Profits After Taxes, Weighted Average Cost of Capital and value of total capital invested. In the Czech Republic reported to be use EVA equity.

In the manufacturing industry in some sectors, where EVA is positive or increases. In the construction industry it is always negative. EVA is growing in the manufacture of machinery and equipment. Wood processing industry is negative during these years. In the Pharmaceutical industry is EVA positive during 2012 but next year is negative. And finally is positive in the year 2014.

The largest increase of EVA is in manufacturing of machinery and equipment, tha value is -1,366,644 million CZK. EVA jumps to the amount of 2,155,997 million CZK in 2013.

The next type of industry is the construction industry. Civil engineering had an positive EVA in 2012, but next years it s negative. Building construction is negative long-term.

Next part of this paper compared two companies – Žďas, Inc. and PSJ, Inc. The first of them is working whithin the engineering industry and the second one is working in the construction industry. The highest retained earnings had PSJ, Inc. In 2014. The highest positive GVA can be observed for the company Žďas, Inc. during year 2012. Value added does not cover disposal value among the stakeholders of both companies, because profit is consisted of sales of fixed assets and material. There is one exception for PSJ, Inc. in 2014. Value added is higher in this year and other indicators are almost the same

Possibilities and Trends for Impact Investors

Dr. Daniela Majerčáková**,** Comenius University in Bratislava, Faculty of Management FM CU, Bratislava, Slovak Republic, daniela.majercakova@gmail.com

Mgr. Alexandra Mittelman, Comenius University in Bratislava, Faculty of Management FM CU, Bratislava, Slovak Republic, Alexandra.mittelman@fm.uniba.sk

Abstract

The aim of this paper is to describe and analyze what possibilities investors who are interested in additional impact of their investments have. As we already know, impact investments should affect the product portfolio of each included participant in every important sector. For this reason it is more than important to focus our view on description of trends in the alternative investing possibilities. Individuals, institutions, investment companies, money managers and financial institutions that practice sustainable, responsible and impact investing seek to achieve long-term competitive financial returns together with positive societal impact. These strategies should be applied across assets classes to promote stronger corporate social responsibility, foster businesses or introduce products that will yield community and environmental benefits or build long-term value for companies and their stakeholders. Impact investments are intended to create positive social or environmental impact beyond the financial return and they create a new asset class. Impact investing, or we should say, social investing has gained traction among a wide range of investors, including foundations, private managers, individuals, commercial banks and development finance institutions. We are assuming that investors have a wider range of expectations for impact investment financial returns what estimates significant market opportunity for impact investment in various parts of financial markets.

Keywords: impact, trend, possibilities, product portfolio

Introduction

Impact investing is a type of investing that aims to generate specific beneficial social or environmental effect in addition to financial gain. Impact investing is a subset of socially responsible investing (SRI) but while the definition of socially responsible investing encompasses avoidance of harm, impact investing actively seeks to make a positive impact by investing. On the other hand, we should state that impact investing is to help reducing the negative effects of business activity on the social environment, and it can be considered as an extension of philanthropy. According to the Global Research by the J. P. Morgan "Impact Investments: An emerging assets class" we should agree with the definition of impact investments as a new alternative for channeling large-scale private capital for social benefit. With increasing numbers of investors rejecting the notion that they face a binary choice between investing for maximum risk-adjusted returns or donating for social purpose, the impact investment market is at a significant turning point as it enters the mainstream. From this perspective of theory in the practice, investors involved have very few places to go to learn how to invest for impact. Possibilities for investors are not very wide, for example accredited investors should join ImpactBase, ImpactAssets 50, European Venture Philanthropy Association, GIIN membership group or foundation Mission Investors Exchange. For the early stage investors, there is a possibility to participate in impact investing angel networks like Investors´Circle and Toniic as well as in regional groups. Impact investing includes many different forms of capital and investment vehicles. The majority of impact investing is done by institutional investors but a range of socially conscious financial service companies, web-based investment platforms, and investor networks currently offer individuals an opportunity to participate in it. One major possibility is microfinance loans, which can provide small-business owners in emerging nations with startup capital. As environmentally and socially responsible practices tend to attract impact investors, companies can benefit financially from committing to socially responsible practice that investors also tend to profit from. Impact investing practice is mostly important for younger generations, who want to get back to society, so this trend is likely to expand as these investors gain more influence in the market.

Impact Investing

Impact investing is no longer the new kid on the block. Leaders like the Ford Foundation, MacArthur Foundation, the Rockefeller Foundation and others have helped to pave the way; building the impact of investing in ecosystem by sharing lessons they have learned over the years – even the hard ones - and by finding ways to invest alongside other investors. (Cynthia Muller)

Impact investing refers to investments "made into companies, organizations and funds with the intention to generate a measurable, beneficial social or environmental impact alongside a financial return (Global Impact Investing Network. "About Us" 2013, retrieved 15 December 2015). It is form of socially responsible investing that serves as a guide for various investment strategies (Lemke and Lins, Regulation of Investment Adviser, §2:158, Thomson West 2013). Among the best-known mechanism is private equity or venture capital. Social venture capital or patient capital and impact investments are structured similarly to those in the rest of the venture capital community.

By analyzing the inherent logics and rationalities, this framework strives to acknowledge financial returns alongside social impact while simultaneously considering implied risks. At the same time it is flexible enough to deal with various approaches to measure social, environmental and corporate governance risk and return factors, an important necessity to serve the broad range of actors and different logics in the field. Over the last couple of years, the field of impact investments has advanced in terms of market structures, and has involved participants and investment vehicles. Among the diverse set of streams within the social investment market, the progress achieved in impact investing has received exceptional attention in practice and media. (Brandstetter, L. & Lehner, O.2014).

Impact investing challenges, the long-held views social and environmental issues should be addressed only to philanthropic donations, and that market investments should focus exclusively on achieving financial returns. The growing impact investment market provides capital to the world's most pressing challenges in sectors such as sustainable agriculture, clean technology, green real estate, supply chain services, technical assistance services, energy, microfinance, and affordable and accessible basic services including housing, healthcare, and education. From the perspective of this markets investors like individuals, private financial and for-profit institutions, philanthropic institutions and last but not least governments are seeking for outcomes like jobs, educations, environmental sustainability, improved social program outcomes, economic opportunity, new social enterprise business models or new investment opportunities. Impact investment has attracted a wide variety of investors; concretely (1) diversified financial institutions; (2) pension funds; (3) insurance companies; (4) large-scale family offices; (5) fund managers; (6) private foundations making program and mission-related investments; (7) development or specialized financial institutions; (8) private financial institutions; (9) individual investors. Private financial institutions have the increasing interest in investing into social businesses and bring the expectations of social and economic return. On the other hand, public authorities are becoming reluctant to invest in the projects of innovation; they do not perform their own duties in supporting the social business if the existing projects are financed by the philanthropic organizations or private investors. Some organizations therefore fight with the possibilities of finding the investor or gaining the necessary capital for their innovation projects and ideas. Private investors expect demonstrable social and economic return on investment, and this is the factor that forces public authorities to expect the same effect from their own investment.

As we can see, the common matter of facts from the perspective of impact investment markets and investor's intent to create a positive impact; should create core characteristics of impact investing. This practice is defined by the following core characteristic: investment with return expectations, intentionality, range of return expectations and assets classes and impact measurement. All of this core characteristic should be defined, combined and bringing together the positive impact for each investees, investors and outcomes. The main themes, which they pursue are financial inclusion, employment, economic development, sustainable living, agriculture and education. From the

perspective of J. P. Morgan's survey report "Global Social Finance. Eyes on the Horizon" we learnt that progress was made in 2014 across several indicators of market growth, including investor collaboration, impact measurement practices and pipeline quality. Relative to the last year, significant progress was indicated in collaboration, availability of investment opportunities, and availability of capital across the risk/return spectrum.

While certain types of impact investments can be categorized within traditional investment classes (such as debt, equity, venture capital), some features dramatically differentiate impact investments. Together with Global Research "impact investments an emerging asset class", we argue that an assets class is no longer defined simply by the nature of its underlying assets, but rather by how investment institutions organize themselves around it. Specifically, we propose that an emerging assets class has the following characteristic: (1) requires a unique set of investment/risk management skills, (2) demands organizational structures to accommodate this skill set; (3) they are serviced by industry organizations, associations and education; (4) encourages the development and adoption of standardized metrics, benchmarks, and/or ratings. These characteristics are present for such asset classes as hedge funds or private equity, which channel significant capital flows, as a result. With each of these indicators having materialized, we argue that impact investments should be defined as a separate asset class.

The risks for impact investments are similar to those for venture capital or high yield debt investments, with heightened reputational and legal risks, particularly in emerging markets where regulatory infrastructure can be onerous and the rule of law is less well defined. When we evaluate impact funds, the more unique risks to consider include political, currency and liquidity risk. (Linton, J. 2015: Impact Investing Funds: What are the Risks) Political risk refers to the risk related to instability in countries. On the other hand, diversification approach of many funds may also possibly reduce the political risk by investing only in one region or even a single country. Also a regional or country focus may allow investment managers to understand better, monitor and mitigate the political risk exposure of their investments. Most important in any international investment and also particular importance in impact investing has currency risk. Many impact investments are in countries with volatile currencies and currencies that may lack hedging mechanisms. To reduce significantly currency risk, it is better to search for countries that have less volatile local currencies or countries that have adopted the dollar or euro as their commerce currency. Hedging currency risk depends on whether there is liquidity available in the currency. The most common hedging instrument is the non-deliverable forward, which allows investors to lock in a forward exchange rate at a given time in the future. Liquidity risk may be difficult or impossible to exit an investment. This brings up the important question of whether the impact fund invests in debt, equity, or in another instruments. Debt investments generally carry minimal exit risk as the investee makes payments directly to the fund. Equity investments can carry large exit risks as developing markets may not have an accessible way to exit an equity investment, such as a liquid secondary market. With risks properly mitigated, the impact investing funds can offer attractive yields to investors and generate positive social or environmental impacts.

An impact investment must constantly balance the dual imperative of generating positive social impact and profit. Some impact investment business models, especially those employing high-volume, low-cost approaches are able to drive financial return and social impact together with impact and profit correlation as the business expands. However, it would be naïve to believe that these two imperatives have never been in tension. Indeed, within the microfinance sector, some concerns about mission drift are already beginning to appear.

In addition to having different reasons for measuring impact, participants in the impact investing industry will use the measured data in different ways. Companies want to understand, track and report of their social performance, and compare their performance with that of their peers. Fund managers also need a system for managing the variety of social performance information they receive from their portfolio companies. In defining measures of social impact, these standards must find the line between the level of detail that is too onerous to collect and one that is too superficial to be useful. A common language for social performance metrics will encourage transparency, credibility

and comparability, just as the International Financial Reporting Standards provide transparency and comparability across financial performance reports. The standards included metrics related to the social aspects of business operational practices as well as of its products and services. The standards are overseen by an independent governance body that provides guidance towards the ongoing advancement of the framework and ensure its alignment with existing best practices.

Trends for Impact Investing

In the context of social investing in this time of economic and political changes and transformations of business challenges we expect to see four main trends to take hold (Cynthia Muller):

(1) Increasing investment by smaller foundations and family offices, and increasing engagement from wealth advisors. By some estimates, more than trillion USD will transfer from baby boomers to millennials over next 30 years, the largest wealth transfer in history. Family offices and wealth advisors are reporting more interest in impact investing from clients.
(2) Increasing clustering of investments in particular sectors. We expect that momentum for climate-related investments to increase as more products and offers become available. We also expect to see similar movement in education and health-care investing, as potential impact investments challenges.
(3) Multi-stakeholder collaborations. It is particularly exciting to see that impact investing has begun to expand beyond a core group of foundations and other socially - oriented investors and to attract a wider array of actors. Banks, corporations, and even pension funds are seeking ways to invest with different partners so that their investments yield social as well as financial returns. The tremendous growth in interest in activities related to pay-for-performance contracts – such as social impact bonds and development impact bonds – are a key example. Investors see these as the potential tools to engage multiple stakeholders from different sectors to leverage government and private resources to generate social impact along with financial returns
(4) More data. Performance data – actual returns – represent perhaps the field's most importance piece of missing information. For more funders and investors to routinely engage in impact investing, they will need to see a more complete track record, generated through better systems for tracking and broader reporting of both financial and social returns. Moreover, it is expected to see more foundations and individuals sharing the characteristics and performance of their portfolios. As a shared base of knowledge and best practices continues to grow, we can streamline the investment process, reduce transaction costs and continue to make impact investing accessible more widely.

As interest and allocations to impact investments continue to rise, we are able to highlight these sectors are trends in impact investing: housing, microfinance, financial services, energy, healthcare, food and agriculture. In the past it was microfinance, which was leading the impact investing strategies. This divergence is most likely an attempt made by impact investors to diversify their strategy given the historical prominence and domination of microfinance in their portfolios.

Conclusion

"As investors add the third dimension of impact to risk and financial return in their decision making, we expect there to be a considerable pool of capital looking for opportunities to invest in achieving measurable social impact." (Impact investment: The invisible heart of markets, 2014)

The biggest opportunity for social investing seeks to strengthen peoples' current and future capacities and improve their opportunities to participate in society and labor market, and, of course, calls for investing into children and youths to increase their opportunities in their life. Each of this opportunity for social investing firstly needs the changes in society in the meaning of social innovations and providing social services. They may actively seek out investments – such as community development loan funds – that are likely to provide important societal or environmental benefits.

Despite rising allocations and interest in impact investing, there are several constraints that investors are facing. First opportunity echoed by investors is the lack of appropriate capital across the risk/return spectrum. Even within impact investing, there is a spectrum of capital that adheres to various impact and return appetites. The second investment opportunity deals with the flow of track records. Due to the nascent market, investors tend to rely on word of mouth and informal networks. The third biggest opportunity is challenge in the difficulty in exit strategies. Impact investing is still in its infancy for the most of its part, and likely many alternative investments and patient capital is needed until capital gains are to be realized. As a young sector, impact investing may be challenging, but once track records of success and proof points are realized, there will be a greater opportunity for impact investing to garner interest and capital from investors.

Abstract

Knowledge Management (KM) projects are socio-technical systems that enable knowledge activities and ensure that the right knowledge gets to the right person at the right time. The growing number of KM applications confirms the need for a performance measurement model able to assess the diversity of KM initiatives in order to rationalize their usage. To the best of our knowledge, a generic KM model for performance measurement fitting any kind of KM projects is missing in the literature. Instead, existing approaches are specific to a particular KM project or assess the overall KM of the organization. In this paper, we propose a KM model for performance measurement that is built on existing KM models literature and enhanced with theoretical findings. It also follows the reference modelling design process in view of producing a high quality model.

Keywords: knowledge management model; performance measurement; reference model;

1 Introduction

Knowledge is recognized as a key resource for organizational success. Making the best use of this resource is an important concern for both researcher and practitioner (Barthelme-trapp and Vincent 2001). To obtain all Knowledge Management (KM) benefits, it is necessary to measure the KM performance (Ragab and Arisha 2013). Since there are no standards in measuring KM performance, many approaches and models are proposed in the literature. They argue that KM performance measurement follows three phases: defining the KM objective for which the performance will be measured, modeling the components of the KM to be measured, and identifying a set of relevant measures for each component of the model (Wong et al. 2013; Oufkir et al. 2016). However, literature on the KM performance measurement still raises some critical constraints to be considered when creating a KM performance model:

- **Diversity of KM applications**. Along with the growing number of KM applications, performance measurement design becomes more constraining. Dealing with the diversity of KM projects requires either multiple performance measurement models or a generic one that can be applied to all settings (Del-Rey-Chamorro et al. 2003). However, no generic KM project performance measurement model has yet been proposed in the literature while a significant number of approaches deal with specific project assessment or assessment of the overall KM organization (Wong et al. 2013).
- **Variety of KM models**. Due to the broadness of KM field and the lack of KM standards, existing KM models vary in scope and focus. A widely adopted taxonomy identifies three trends in designing KM models (Dudezert and Agnes 2006; Wong et al. 2013; Handzic 2011): the first one is based on the understanding of knowledge concept, the second approach focus on the knowledge flows in the organization, and the third approach considers the social-technical aspect of KM and related impact factors. Indeed, each approach is valuable in itself, but constitute only a partial view of KM. (Handzic 2011) raises the need of a unified model that incorporates the three previous views. Also he tackles the need to develop a deep understanding of each KM core terms.

- **Lack of scientifically proven KM model.** The analysis of the KM models literature leads to the conclusion that little academic work exists on designing a KM model in a scientific manner. Indeed, recent studies criticize the often missing model validity check and the lack of quality concern in designing models (Matook and Indulska 2009). This is particularly true for KM model design. To the best of our knowledge, KM model design is based on both KM requirements and qualitative review of existing KM models. It is usually subject to empirical application to check model effectiveness (Handzic 2011) but is rarely subject to quality validation. Therefore, there is a need to integrate KM model quantitative valuation in designing KM models.

Thus our work focuses on the following research questions (RQ):

- RQ1: is it possible to design a generic KM model able to assess diverse KM projects?
- RQ2: what are the key elements that a generic performance measurement KM model should cover?
- RQ3: how to design our generic KM model in accordance with the scientific design method to ensure its validity?

To address these issues, we propose a design of reference model (RM) for KM performance measurement (KMPM) that draws from both the literature review of existing KM models as well as the performance measurement requirements. The model design follows the quality driven design approach: a five step design methodology that provides a model quality assessment based on predefined RM quality criteria. Our reference model is able to assess both the overall organizational KM and any specific KM project thanks to its generic process and KPI sub models. Such reference model provides a common formalization for researchers with a global view, theoretical background and precise terminology. Practitioners also need this conceptual model to help them to better assess KM initiatives both jointly and separately and to identify those that are adequate to their context.

The remainder of the paper is organized as follows. Section 2 provides an overview of related work about knowledge management modeling. Section 3 includes an introduction of the reference modeling design and presents the adopted design steps of our model. Section 4 summarizes our contribution and points on some future work.

2 Related Work

According to (Davenport and Prusak 1998; Alavi and Leidner 2001), KM refers to methods, mechanisms and tools designed towards preserving, valuing, creating and sharing knowledge with a view to furthering the organization's objectives . Implementing a KM project in an organization consists of implementing a socio-technical system that is able to ensure KM processes.

Reviewing literature on KM models shows that researchers suggest three major components for KM (Dudezert and Agnes 2006; Wong et al. 2013; Handzic 2011):

- Knowledge resources: refer to the whole organization knowledge (Wong et al. 2013). According to Davenport (Davenport et al. 1998), the knowledge resources include: human capital (e.g. employee staff, customer and suppliers), knowledge capital (quantity and quality of knowledge possessed by the firm) and intellectual property (the product of knowledge creation that generates value).
- KM processes: it involves activities related to knowledge flow in the organization considering knowledge dynamic nature (Alavi and Leidner 2001).
- KM factors: other than KM resources and processes, researchers consider the importance of some influencing factors for the support and the success of KM initiatives (Ragab and Arisha 2013), (Ale et al. 2014; Wong et al. 2013).These factors include cultural, structural and technological aspects such as trust culture, centralization structure and IT support.

Nevertheless, the literature presents evidence of the relationship between knowledge resources and knowledge processes. (Handzic 2011) argues that knowledge resource perspective is deeply anchored in the process perspective as knowledge resources are transiting through the KM processes; they represent their outputs. Besides, the performance measurement is more of dynamic knowledge matter than static knowledge (Lerro et al. 2012; Nonaka et al. 2000). Accordingly, we do not consider

knowledge resources as a stand-alone perspective whereas we assume that understanding knowledge is very important in order to achieve proper knowledge process model design. Therefore, the knowledge view yields some important observations:

- Knowledge exists in many forms in the organization. At least two forms of knowledge are particularly valued: the tacit knowledge that is rooted in action, experience and involvement in a specific context; it is composed of beliefs, know-how and skills. And the explicit knowledge that is articulated, codified and communicated in symbolic form and/or natural language (Alavi and Leidner 2001). Both forms interact permanently in the enterprise through many conversion mechanisms (Nonaka et al. 2000).
- Knowledge exists in the organization in different levels (Nonaka and Takeuchi 1995; Grundstein 2012).We distinguish first the organizational level that is shared among distributed actors belonging to the same organization (e.g. knowledge incorporated within routines, models and regular and predictable behaviours). The second one is the collective knowledge which is owned by a group of persons that share a mutual identification, actions and projects (e.g. communities). The last one is the individual knowledge which is the personal and intangible knowledge. It encompasses people abilities, know-how and know-what…

The KM factors perspective emphasizes that knowledge mobilization within organization is strongly context-sensitive. It is made up of two separate attributes related to the socio-technical aspect of KM: the technical factors that consist of the project infrastructure and supporting technologies, and the social factors that depend on the dominating culture, the KM structure and the human aspect. Several authors study KM factors theoretically and empirically and come to a firm agreement on their identification (Ale et al. 2014; Wong et al. 2013), (Ragab and Arisha 2013).

Regarding the KM process perspective, literature shows a broad range of models. (Nonaka et al. 2000) propose the SECI model that presents four ways for knowledge types conversions: socialization (tacit knowledge to tacit), externalization (tacit to explicit), internalization (explicit converted into tacit) and combination (explicit to explicit). SECI model introduces the BA context as a KM factor, a Japanese term meaning “place”, that refers to the specific context (place, energy and quality) needed for the effective knowledge flow. On the other hand, the knowledge circulation process (KCP) proposed by Chang (Chang Lee et al. 2005) consists of knowledge creation, knowledge accumulation, knowledge sharing, knowledge utilization and knowledge internalization processes. The basic assumption behind the KCP is the work of Alavi and Ledner (Alavi and Leidner 2001) that considers knowledge having multifaceted characteristics: object, state of mind, access to information, process and potential for influencing future action. The KCP and the SECI models are the most used models for KM performance measurement purpose. (Grundstein 2012), in turn builds a model composed of four generic processes: identification, preservation, recovery and valuation of knowledge. These processes respond to the recurrent knowledge problems recognized in the organization and provide a detailed description of knowledge flows by breaking down each generic process into more specific sub-processes. Other models presented in the literature are more empirical and depict the author point of view about KM activities. Knowledge management process cycle proposed by (King 2009) is an example of such models.

On the basis of the previous analysis, studied KM perspectives stress on the following points:

- Most of reviewed models were developed under a special KM perspective or as a solution to a particular organization problem.
- Reviewed models globally share the same central idea that KM processes depict the knowledge flow in the organization. However, the delimitation of process scope is controversial with the exception of core functions (creating, preserving and transferring knowledge).
- KM processes involve interactions and conversions between knowledge in all its forms: the tacit and the explicit type besides the individual, the collective and the organizational aforementioned levels.
- Two models seem particularly interesting for the performance measurement purpose among all reviewed KM process models: the SECI model (Nonaka et al. 2000) that considers KM processes as knowledge forms conversions, and the Grundstein process model (Grundstein 2012) that defines generic processes and sub processes in accordance with organization knowledge problems. Combining both approaches while designing a KM model can contribute to our requirement in

twofold: it structures KM project according to Knowledge problems and knowledge forms and it facilitates the performance measurement through the KM process decomposition to the desired granularity.
- A context that brings together cultural, structural and technological factors is conducive to the deployment success of the KM. This aspect was largely discussed in the literature that shows a broad agreement on these factors identification.

On the other hand, performance measurement relies basically on performance measures which provide a benchmark of progress towards the performance achievement. Existing work on performance measurement applied to KM stresses on the importance of KPI and categorize them in different ways (Wong et al. 2013). Indeed, (Kuah et al. 2012) states that KM can be viewed as a system based on KM processes that consumes inputs and produce outputs, and that these variables can be used as a proxy to measure KM performance. Del-Rey-Chamorro (Del-Rey-Chamorro et al. 2003) addresses two kinds of KM measures : core outcomes in the strategic level and performance drivers in the operational level. Goldoni and Oliveira (Goldoni and Oliveira 2010) suggest that KM metrics can be divided into process and result metrics. This suggestion aims to measure KM performance at different levels of the organization. Globally, all previous studies agree that KPI is an important element for performance measurement and that it monitors significant KM components.

3 Design of the KMPM

In this section, we present an overview of the reference model design. Then, we focus on a special reference model design approach that we apply to the case of knowledge management reference model design.

3.1 Reference modelling

Generally, a Reference Model (RM) serves as a starting point for developing solutions according to a concrete problem in a scientific manner (Scheer and Nüttgens 2000). RMs refer to aggregated, generic or theoretical models that needs adaptation for a specific concern (e.g. a project development, an enterprise) (Andreas and Frank 2016).

Since a low quality RM can be damaging for the organization, a considerable number of works focus on guiding the development process to achieve a better RM quality (Winter and Schelp 2006),(Andreas and Frank 2016; Matook and Indulska 2009; Thomas 2006). Reviewing research on the subject shows a list of shared RM requirements. (Andreas and Frank 2016) presents these requirements as a five step design methodology (cf. Fig 1).

Phase 1 is **the scope definition** which involves the identification of the scope and the target model. In the second phase, **the literature review** on the subject is gathered and analyzed. Phase three consists of **the reference model construction** and design in an iterative way, based on the obtained results from the prior phases. The established model needs a **quantitative evaluation** which is the subject of the fourth phase. Lastly, an **empirical assessment** is performed within a real-world environment.

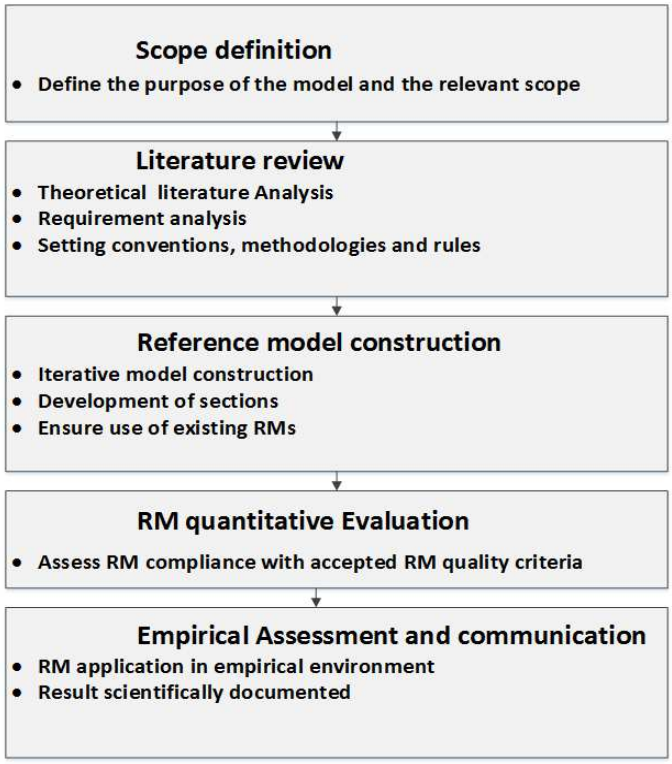

Fig 1. Reference model design steps

3.2 Design Phase 1: Scope of the model

Performance measurement is an ultimate purpose that should be taking into account while building the KMPM model. It should meet the three requirements (RQ 1-3) mentioned in the introduction.

3.3 Design Phase 2 : Literature review

Based on the literature analysis, we depict the most important KM key concepts within the research field as sub models. Therefore, we build a model that entails three perspectives: process sub-model, factors sub-model and KPI sub-model. We state that agreement is reached concerning KM factors. However, KM processes delimitation should be considered carefully as they represent interactions between knowledge forms. Thus, it was decided to consider the processes according to the organization knowledge problems and to proceed to their decomposition in view of knowledge forms conversion. The knowledge forms and related knowledge conversions are presented in Fig 2.

We select the Unified Modelling Language (UML) and especially the class diagram for the presentation of the reference model. For the process sub-model, the flow chart notation is used.

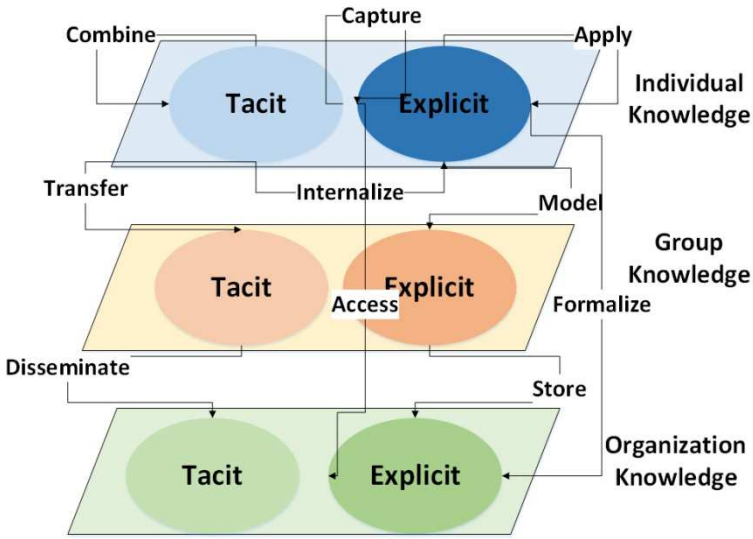

Fig 2. KM sub-processes and knowledge conversions

3.4 Design Phase 3: Reference model construction

The proposed RM summarizes the most important research results and provides a common KM enterprise model in its different aspects. It embodies three perspectives (cf. Fig. 3):

- KM process model: is derived from the qualitative literature analysis and based on inductive results,
- KM context model: encompasses the well known KM factors
- KPI model: this component plays an important role as it provides measures for each perspective. The final project performance indicators are the aggregation of all perspectives.

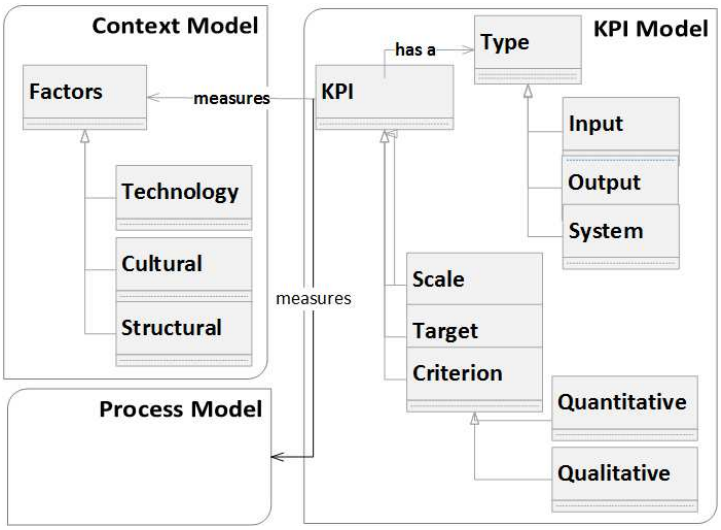

Fig 3. The KM reference model

Every KM project is an instantiation of one or more KM processes; it is influenced by the organization factors and is monitored with a set of KPIs. Fig. 5 provides an excerpt of the reference model for a sample KM process.

The process model perspective

The process model is built mainly on literature models (Grundstein 2012), (Ale et al. 2014), (Nonaka et al. 2000), (King 2009), (Heisig 2003). It is composed of four generic processes that are decomposed to several sub-processes. Hence, **identification** process encompasses identification and location, **preservation** process comprises the acquisition of knowledge, its modeling and its formalization in addition to the store sub process, the **recovery** process contains the access, the application, the combination and the creation of knowledge, and lastly the **knowledge update** process (cf. Fig. 4). These sub processes represent knowledge problems and conversions between knowledge in all its forms.

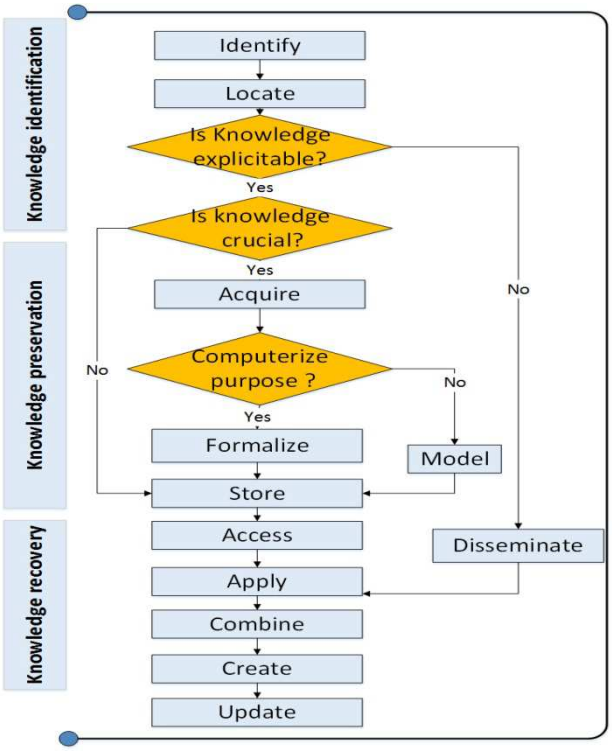

Fig 4. The KM process model

The KPI model perspective

The KPI perspective operationalizes the other KM perspectives. KPIs monitor the performance of a KM project according to both KM processes and KM context aspects. All measures in this study are based on existing KM performance measurement instruments and KM literature (Wolf and Tendron 2014; Robertson 2003; Hoss and Schlussel 2009; Wong et al. 2013; Don 2001; Heisig 2003; Ley et al. 2010).

For KM processes, KPIs are grouped into two categories (Hoss and Schlussel 2009; Lee and Choi 2003): input and output. Each KPI has its own set of measurement criteria: scale, range, current and target value. It can be either quantitative or qualitative.

The context model perspective

KM context corresponds to the factors that impact the success of KM project. According to (Gold et al. 2001), technology, culture, strategy and KM structure are the most influential factors on KM project success.

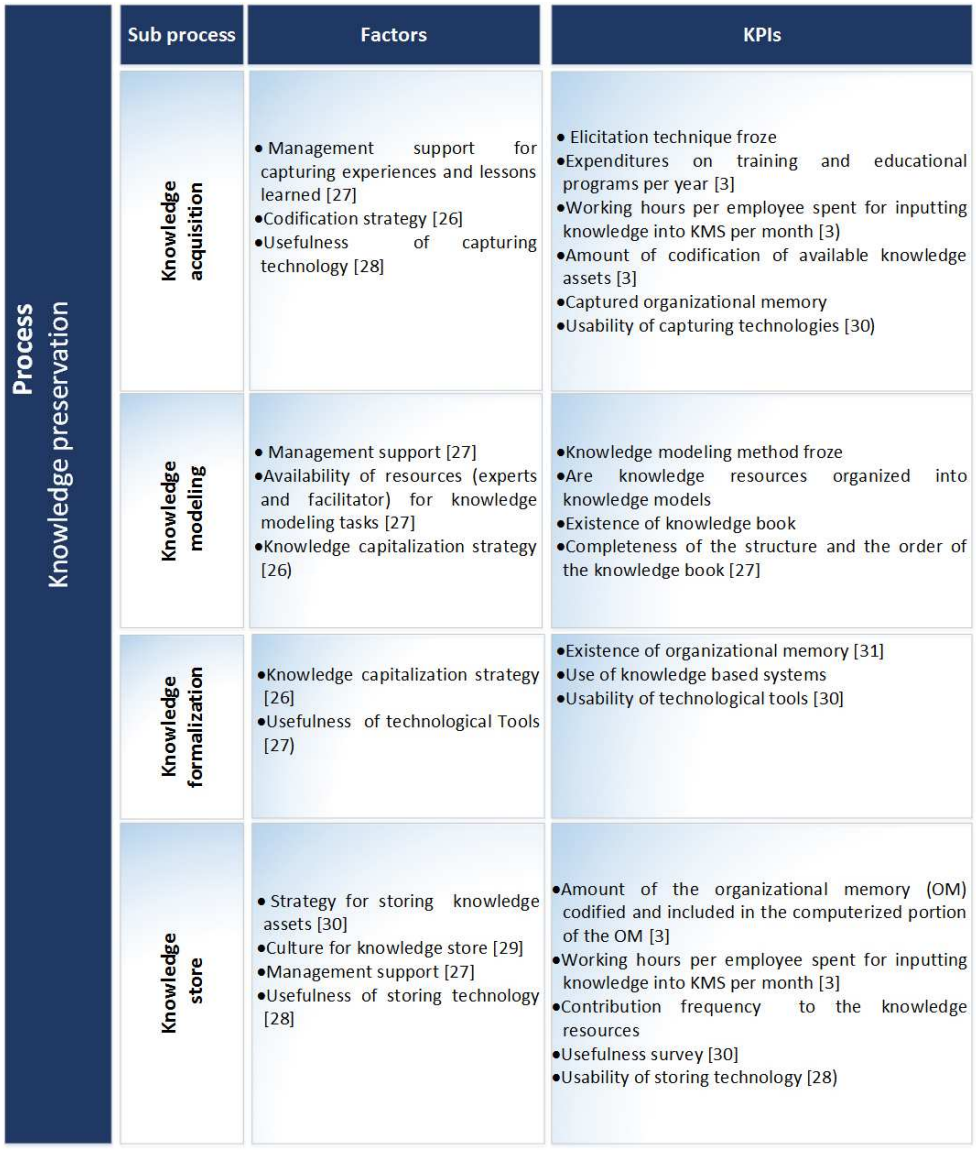

Fig 5. The KM model excerpt

3.5 Design phase 4: Quantitative evaluation

Within this step, we aim to assess the overall model and test its compliance with the accepted RM quality criteria. We adopt the quality function deployment (QFD) based approach proposed by Matook (Matook and Indulska 2009), which is an adaptation of the initial QFD to the RM design context. The QFD method is used originally for products and services to transform the qualitative user demand into quantitative parameters in order to deploy methods for achieving the design quality. Matook (Matook and Indulska 2009) reports that among all proposed RM assessment quantitative methods in the literature, it is the only one that provides both the RM quality attributes, an assessment method and a proposal of application.

Defined reference modeling quality attributes are:

- Generality: the degree to which a RM is usable in different cases.
- Flexibility: the ease with which the RM accomodates change from initial requirement.
- Completeness: the degree to which designed RM covers all predefined scope.
- Usability: the ease of use, adaptation and application of the reference model.

- Understandability: the clarity of concepts, purpose and structure of the RM

The QFD based approach involves developing a matrice referred as "The House of Quality" (HoQ) that incorporates RM quality attributes (horizontal dimension), RM development phases (vertical dimension), the center of the house which assess the impact of the RM development phases on the RM quality attributes and the user perceptions (cf. Table I).

Table 1. the QFD based approach from (Matook and Indulska 2009)

			RM development Phases				
		User importance ratings	Scope definition	Literature ***review***	***RM*** construction	***Quantitative*** valuation	User ***Fulfillment Ratings***
RM characteristics	**Generality**						
	Completeness						
	Flexibility						
	Understandability						
	Usability						

The quality measure is calculated based on the product of user assessment of the requirements importance and the completeness of the development phases (as reported by the RM designer). Therefore, as we follow the RM design steps for our model construction, we assume that designer rating have a high value. Instead, full rating is not obtained unless we test the model with empirical applications and thus obtain the user importance ratings and fulfilment ratings.

4 Conclusion

This paper presents a KM reference model for knowledge management that responds to the performance measurement requirement. This study provides three main contributions: first, our research reviews the literature on RM design in order to determine the best development approach that results in a high quality RM. Our proposed model follows the identified development process. Secondly, our model is built on KM theoretical foundations. It entails three sub-models :i) a process sub model derived from the KM model literature review and enhanced with literature analysis and logical findings, ii) a KPI model that provides KM project measures according to the performance measurement need, and iii) a context sub model that represents the KM influencing factors. Thirdly, the KMPM is able to assess both the overall organizational KM and the diversity of KM projects unlike existing models that are designed either for assessing the KM of organization or a specific KM project.

Our work is relevant in twofold: firstly through designing a KM reference model with the quality concern, this can be a significant step toward field standardization. Secondly, by filling the literature gap on KM performance measurement and proposing a KM model that assesses all kinds of KM projects.

The limitation of the study is related to the full design process application. In fact, we propose a five step design approach for the RM design. Meanwhile, the latest step which concerns empirical application is not addressed in this paper. This is due to the fact that most of existing KM models claim to be empirical, so we focus on the theoretical aspect in order to broaden the model scope.

Future work may consist on empirical validation of the proposed model which is a part of an overall KM performance measurement framework. A multiple case study will be performed to obtain insights about reference model validity and the global framework reliability.

Abstract

In this paper we propose that generation of business model concepts could be a long-term integration tool to learn and develop entrepreneurial skills during long-term self-study. A concept of business model is regarded as a right set of open-ended questions. We propose formulation of these open-ended questions by using former knowledge in pedagogical science of how to use open-ended questions in education. The developed sufficient set of open-ended questions in the frames of "e3-Value" business model ontology and specific to entrepreneurship can be guiding tool for self-study of entrepreneurial skills. The self-study guiding-tool was tested on students by arranging short-term introductory course with follow-on meetings to track students' self-study of entrepreneurial skills. The proposed approach can be applied to solve problem how in a cost effective manner to increase number of potential self-made entrepreneurs around innovation clusters in development countries. Cost effectiveness mean that short-term courses are just navigation points in the long-term self-study of potential self-made entrepreneurs.

Keywords: business model concept, entrepreneurial skills self-development

Introduction

In the previous research by Laptev et al. (2014), we formulate the sufficient number of competencies and skills that are critically important for innovative entrepreneurs. They form two groups: cogitative (creativity, intuition, analyticity, flexibility of thinking, risk tolerance and decision-making) and personal (pro-activity, ambition, motivation of achievements, competitiveness, perseverance, self-confidence, focus on the result, optimism, perfectionism). To develop that mix within a reasonable space of time available in a classroom is an extreme trial, though. It appears to be a great challenge to find efficient approach and set of training instruments when ones come to a point how to develop those set of personal competencies as well as specific professional ones in a frame of a course. Instructors are traditionally great of delivering management science content and analytical instruments for individuals in class, but entrepreneurial "know-how" is the other side of education story that require constant innovation in approaches. Paradigm of learning by doing and a team work/homework extends and enhances the effect of in-class development of entrepreneurial skills. However, there is a risk that after courses people get back to their behavioral habits even having new knowledge and training experience. Entrepreneurship is a way of how individuals behave by identifying and seizing opportunities. To develop such behavior an individual should accept the approach as a life-long learning course through self-study with some navigation points in class sessions.

Tool to Develop Entrepreneurial Behavior and Skills

We examine the general goal of increase of the number of community members around innovation clusters in developing countries that are interested in entrepreneurial profession. We frame the study by trying to answer how a potential self-made entrepreneur could develop general professional skills having constraints of short-term courses and limited time spent in class.

Interviews with representatives of management companies of innovation clusters in Russia showed that they couldn't afford to support or to deliver long courses for potential self-made entrepreneurs.

The management companies of innovation clusters use the form of education sessions or short-term courses in partnerships with education content providers. This led to a mismatch between a short-term type of courses for entrepreneurship teaching and "lifelong learning" approach required to gain entrepreneurial behavior and skills. There are multiple discussions and papers addressing the issue of "whether entrepreneurs born or made". The conclusion is that both types of entrepreneurs exist and entrepreneurship is a profession.

Ability to formulate and solve problems is a core professional skill. This ability forms a strong foundation for successful professional operation together with ability to design and evaluate systems to meet economic and social constraints, and in some systems also to meet environmental and political constraints. Profession of entrepreneurship is not an exemption from those must to have abilities to be successful in other professions. However, as any profession, entrepreneurship has its own specific tasks that are solved by means of a number of professional methods well known among innovative entrepreneurs. Those basic professional methods form a platform for entrepreneurial management practices; however, set of professional skills required for each venture behind those methods can be different.

Blank (2013) introduced widely accepted now paradigm of the innovation based scalable startup as a laboratory that went through several predetermined stages and general methods of entrepreneurship to solve to achieve verified innovation based business model. The ultimate goal of the S.Blank paradigm is to create a scalable business model with verified business process and concepts of clients/users/consumers profiles, their needs/problems/pains, a minimal product feature set, and value propositions. Those S.Blank's stages of startup development, the ultimate goal, and experimental nature of the startup creation and its business development have determined corresponding needed professional methods and skills.

Design of business model concepts and following them in verifications may be regarded as this long-term integrating tool for entrepreneurial skills self-study. Generation of a business model concept is a process, each stage of which can be described as an open-ended question and should be finalized by answering it. According to Badger et al (1992), open-ended questions develop complex intellection and generate a number of solutions while class participants search their own way of problem solving. From education point of view, open-ended questions stimulate deeper learning even in unknown context outside a course or classroom, ownership of solutions and their evaluation since there are no predetermined correct answers.

Generation and verification of the business model concepts based on open-ended questions provides a valuable combination of benefits for education purposes:

- Benefits arise from open-ended questions that are interdependent to form a balanced business model concept;
- The business model concepts are benefits themselves, since scalable verified ones are defined as the ultimate goal of innovation startup development
- Benefits arise from obligatoriness of experimenting over and over in a long term to verify business model's scalability.

To generate business model concepts potential self-made entrepreneurs have to get profound understanding in business model operating and design principals. To verify scalable business model concepts potential self-made entrepreneurs must develop sufficient set of skills that will vary among business model concept, thus, could be specific for each one to learn.

We followed the set of features in open-ended questions formulation introduced by Cooney et al (2004) to formulate set of open-ended questions that can sufficiently represent a business model concept and would encourage self-studying of entrepreneurship professional skills.

According to Cooney et al (2004), open-ended questions must have the following properties: (1) involve a significant concept in a professional field that in our case is entrepreneurial management, (2) encourage a variety of responses or reactions, (3) communicate the reasoning process of a solution finding, (4) clearly stated, (5) provide possibility of evaluation.

Our objective was to develop some universal, sufficient but not redundant self-study guide-tool for potential self-made entrepreneurs based on these open-ended question criteria.

According to Mettler (2014) business model designers have to choose a specialized ontology for modeling that are not compatible with each other and some are to certain extend redundant. Looking over different business models ontologies in this paper we pay our attention to "e^3-Value" ontology. In a research study by Mettler (2014) characteristics of this type of business model ontology is a lightweight structure based on very useful and widespread vocabulary. The basic constructs in the "e^3-value" are actors, value objects, value ports, value offerings, value interfaces, value exchanges, value activities and market segments.

Having insight from our experience and guide lines from Cooney's et al (2014) and Mettler's (2014) research study we formulated set of eight open-ended questions that in our assumption is sufficient to represent necessary elements for design of a business model concept:

- what are the profiles of qualified leads as clients, consumers, and users;
- what are their needs, problems, and pains;
- what are the value propositions and a minimal feature set of product;
- what is the component base to deliver the minimal feature set of the product;
- what are mix of promotion channels and instruments to work in them;
- what is the sales structure (process) from first contact to money transfer or the sale funnel concept;
- what are the market trends;
- what is the core competitive advantage of sustainable growth?

However, the work to propose set of open-ended questions in the frames of "e^3-Value" ontology was not sufficient to arrange trial tests or to push potential self-made entrepreneurs to use the self-study guide-tool. For the purpose to arrange test trials and to introduce the self-study guide-tool we designed a frame of the short-term course in the following way.

During first classes a teacher/instructor introduced:

- a significant concept in entrepreneurial management field that is behind each open-ended question;
- reasonable process, showing how to answer those questions;
- principles of how a solution of each question effects solutions of the other ones.

The following classes during the course were devoted to team work and encouraging of students' responses to the open-ended questions to determine their reasoning of designed business model concepts.

Based on students' responses on reasoning and evaluation of solutions, the teacher determined knowledge gaps and facilitated further discussions of concepts behind the open-ended questions and their interrelation. At the end of the course teacher got road maps and commitments from students to verify provided solutions through "out of the lab" experiments. This type of commitment was made publically in front of the classmates and gave additional motivation for consecutive self-study. Also the teacher set a "meet-to-gather" in several months with sort-tem course participants in order to keep community feel of the self-study and supervision of the progress.

The proposed set of open-ended questions that are specific for entrepreneurial management in the frames of "e^3-Value" ontology and the approach to structure the introductory course may be an efficient way to develop entrepreneurial skills in communities. We have already tested efficiency of this method by the short-term introductory course of the self-study guide-tool with following meetings to track students' self-study of entrepreneurial skills.

Our future research includes testing of the proposed method within community around one of the innovation clusters to assess its effect on the rise of the number of people capable of creation and management of innovation based entrepreneurial ventures.

A Micro Analysis by Adoption of Steps to Continuous Audit Missions for Financial Implementation of EU Funded Projects in Romania

Cristina Caranica, Bucharest University of Economic Studies, Bucharest, Romania, cristina.caranica@gmail.com
Ivona Stoica, "Dimitrie Cantemir" University, Bucharest, Romania, ivonas@ase.ro

Abstract

The classical audit mission is being replaced by continuous audit systems according to IIA (2015). In this study we examine theoretical differences between continuous audit and continuous control and monitoring and the first steps in automation of some previous manually processes in audit missions in Romania.
This work is realized in a period when was registered an increase in the utilization of audit and accounting software. Our work is applied on the case of European (EU) funded projects' audit where is a present interest to assure quick, correct and viable results within audit missions presenting opinion according to ISA.
The article is one of the first that studied the missions of continuous audit in order to use it in future missions involving European funded projects. The methodological approach is based on a qualitative method, a questionnaire and interview addressed to ten members of the Chamber of Financial Auditors in Romania regarding the use of this kind of missions for the audit of European funded projects.

Keywords: Continuous audit missions, continuous control and monitoring, European funded projects

Introduction

According to Verver (2008), the difference between the continuous audit missions and the monitoring and control missions is related to the responsibility of the team involved in the process respectively auditors or management.
Essentially continuous audit missions refer to currently missions of audit, which are charged as more effective missions.
The automation of the processes and the accounting that must be the base for the continuous audit mission must be reflected in the accounting and audit standards according to Titera, (2013), Zhang, Pawlicki, McQuilken, & Titera (2012)
Rikhardsson & Dull (2016), in their article mentioned there are studies regarding the impact of technologies in continuous audit for small businesses that can be documented in order to develop continuous audit strategies for project.
The audit legislation in Romania is in process of changing, as a state member of European Union, the Directive 2014/56/EU and EU Regulation no. 537/2014 of European Council and Parliament issued in 2014 is in force from June 2016. These new requirements are related with the economic crisis and the transparency of information of an audit mission in order to give access to the information stocked in current "audit black box", according to Clemente (2016).
In a KPMG study (2012) with 700 firms, the higher transparency of error correction and of the process was mentioned to be reason on investing in continuous audit software.
In this article the objective is to provide a feedback from specialists in EU funded projects from Romania regarding the possibilities of using continuous audit missions in audit of financial documents for EU funded projects. The analysis is using the feedback received after a first period of the process of structural funds absorption (2007-2013).
In the next part of our study are shown the two types of assurances i.e. continuous controls monitoring and continuous auditing with specific empirical observation in Romanian EU funded projects case. In the third part of our study we present the methodology used for finding the opinions of specialists and the determining factors of using continuous audit missions in audit of financial

documents for EU funded projects. In the fourth part of the study we analyze the results of the experiment and in the final part we present the conclusions and limitations of the study.

Literature Review

Gonzalez and Hoffman (2015), mentioned Kuhn and Sutton (2006, 2010) that present studies are supporting the empirical methodology regarding the implementation of the controls and monitoring through systems and continuous audit.

The last two decades interests in research were related to continuous audit Gonzalez and Hoffman (2015), mentioned Groomer and Murthy (1989), Vasarhelyi and Halper (1991), Vasarhelyi, Alles, Kuenkaikaew and Littley (2012) as a solution for auditing a database in increasingly higher data for granting the possibility to assure an opinion through reports available in short term after the transaction were made. (CICA/AICPA, 1999)

The importance of using a continuing monitoring was brought by Sarbanes Oxley that was engaged in order to assure extra controls which provides quality, effectiveness and efficiency.

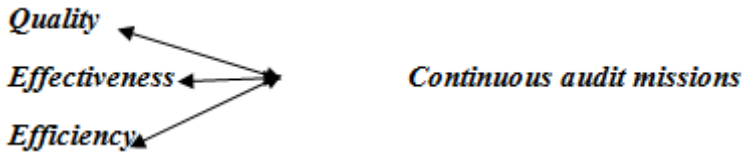

Fig 1: Benefits of continuous audit missions

Verver (2008) mentioned that continuous monitoring controls are assuring complementary controls and helping the continuous audit missions. In our study this is applicable if the verification made by the institutions that are assuring the controls and monitoring of this kind of projects insert controls different than the ones executed by the auditors in their missions.

ACFE (2014) specified that one of the responses to the fraudulent activities is the continuous audit. Moreover, Gonzalez and Hoffman (2015), mentioned Vasarhelyi, Kogan and Alles (2002), Chan and Vasarhelyi (2011), Davidson, Desai and Gerard (2013), Farkas and Murthy (2014) are placing continuous audit above classical audit in the detection of fraudulent events.

Kearns, Barker and Danese (2011) presented a model of forensic continuous auditing where continuous auditing is determining actions of analyzing exceptions, juridical analyze and refine the rules in order to increase control functions and to decrease risk of fraudulent and governance risks.

If Cukier and Mayer-Schoenberger (2013) underlined in one of their studies that in 2000 approximately 25% of information was archived in electronic way but 15 years latter approximately 98% is stored electronically and in our case the documentation for a EU funded project must be stored 100% in electronic so continuous audit missions in this case can be applicable. Another distinct element of our experiment is that according to current legislation in this type of projects audit missions the report can be provided by internal auditors or external auditors. Taking this hypothesis into consideration future research must concentrate upon the improvement of efficiency and efficacy in this particular missions applied on EU funded projects.

In the late 1980's and early 1990's some studies presented the first elements of continuous auditing according to Groomer & Murthy (1989), Vasarhelyi & Halper (1991) and in the 2000's the methodology was established mentioned Brown et al. (2007) and in this period different researchers were presenting possibilities of framework and principles that later were developed. Some of the studies were related with the costs of a continuous audit mission mentioned Alles, Kogan, & Vasarhelyi (2002), Alles, Kogan, & Vasarhelyi (2008) Rezaee et al. (2002) or utility according to Alles, Kogan, & Vasarhelyi (2011). At this phase of the process is considered important to be used in internal and external missions, considered Byrnes, Ames, Vasarhelyi, Pawlicki, & McQuilken (2012).

As studies of Vasarhelyi et al. mentioned (2004) it is the time of empirical analysis, as our study is using.

According to Chiu, Miklos, Vasarhelyi (2014) the process of continuing assurance is suppose to bring changes in:

- Scope of the process;
- The moments of the process;
- The process and the technical approach;
- The outcome of the process.

The adopting of continuing assurance processes is build on the capacity of the auditors in using auditing software as one of the studies presented (Robert and Harold, 2003).

One of the principles of continuous auditing is to build some „rules" to help software to compare the transactions with that rules and to present possible frauds or/and errors. (Vasarhelyi, 2002)

The importance of online connection of the both sides of the process in the continuous auditing (auditor and client) was mentioned in the studies concluded Kogan et al. (1999). In order to function online it is necessary to have real time information and it is important to mention that reason why the continuous missions are characteristic to internal audit more than external audit mission is related with some factors:

- importance of frequency of reporting for the internal audit department mentioned Vasarhelyi, Alles, & Williams (2010), Vasarhelyi, Krahel, & Teeter (2010)
- importance in monitor the risks and control performances was mentioned by De Aquino, Da Silva, & Vasarhelyi (2008).

Practical studies suggested the use of some SAP's (Systems Applications Products) for the analysis of the abnormal transactions according to Kuhn and Sutton (2006), Koskivaara and Back (2007), Santos, Sousa, Ferreira, and Tribolet (2008), Gal (2008).

Practical audit area is considered to be more and more addressed because of the necessity of answering important questions regarding the quantitative and formal part of the matter of using continuous audit. This is because classical audit missions, in relatively short time in which requirements are attributed to these missions, are registering mostly qualitative requests.

Research Methodology

We used the analysis of the content of resources regarding the continuous audit as a main method of research.

Experimental studies were conducted using self-designed survey and interview on this topic with external auditors, members in Chamber of Financial Auditors in Romania.

Following the structure presented in the research of Chiu, Liu, Vasarhelyi (2014), Conceptual map of the Continuous Audit system based on Continuous Monitoring System we presented the appliance of it on the case of EU funded projects. According to the study after 2008-2011 the focus of research for the topics of continuing monitoring was moved from strict technical to usage phase. Our study is following the steps presented by Krahel, (2012) and Vasarhelyi & Krahel, (2011) regarding the importance of formalizing the process in order to reach continuous auditing so the first empirical step is considered to be the projects area and a well-regulated field of EU funded projects.

A very good argument of the study is that the practice is going to present ways in assuring formalization of the processes.

Summary of sample characteristics of interviewees (Fig.3) are presented according to answers received in interview guide with auditors (Fig.4).

Overview of accounting cycle and the related audit process for the first reimbursement claim of an EU funded project - application in Romania (Fig.2) is representing also a result of the study.

Results

In the second period of structural fund absorption (2014-2020), Romania is in the point where it is possible to analyze the means of improving the processes of structural funds absorption in order to ensure higher absorption capacity than that of the previous stage (2007-2013).

In the process of absorbing the population participated through the various roles like: investors, decision factors, employees, specialists, end-beneficiaries and not least as accountants, controllers and auditors.

Our analysis is based on an exercise based on projects auditing experience from 2007-2013 process that can improve along with the other changes in the allocation and uptake of these types of funds for 2014-2020.

Following the adoption of fairly recent computer systems to business accounting and audit of project management, our analysis is based on the possibility of combining these systems so that there is a real-time feedback that determines the minimization of risks in accessing and managing EU funds and increase accessibility for various data controls and audit assignments.

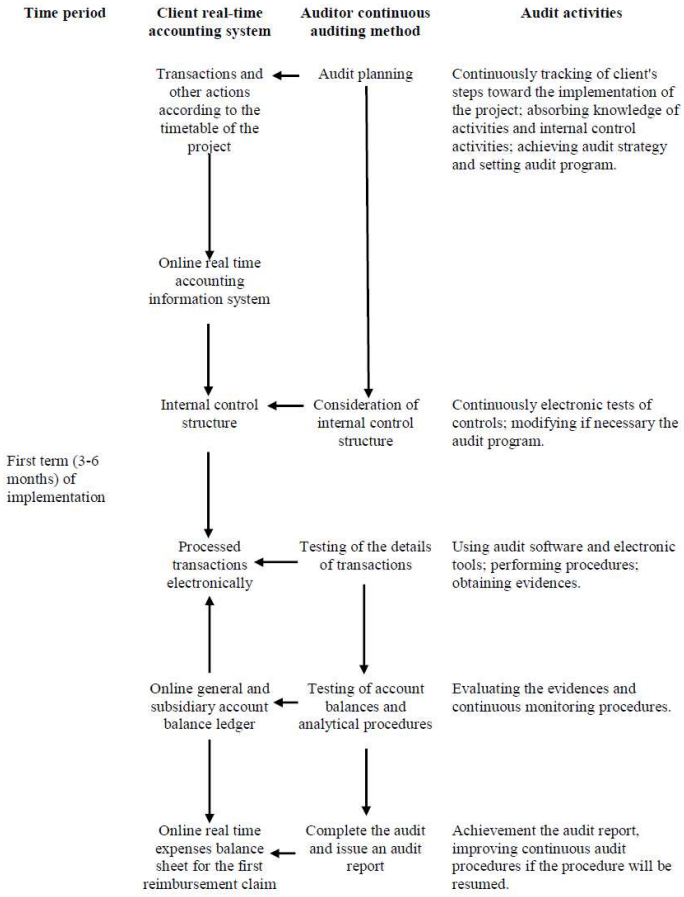

Fig.2: Overview of accounting cycle and the related audit process for the first reimbursement claim of an EU funded project a structured application in Romania

It should be emphasized that the efficiency of a system of continuous audit of financial information relating to an EU project must be even greater as the project is contracted for a large sum.

To ensure project efficiency as ensuring the trust and exact amounts of information can make the difference between a success and a costly failure. For this reason we consider that a continuous audit mission and continuously monitoring of the financial aspects of a project becomes a necessity in this context.

Given that at the moment most of the information is produced and submitted in electronic format and online bind people who are working in accounting and audit engagements for projects financed from EU funds operate with this information and having dexterity in the use of such electronic sources. We must underline here the importance of **well-prepared personnel** in using the latest software in the accounting and audit because persons who do not own such skills can put resistance to change.

Presently Romanian **regulations** obligate beneficiaries and partners in EU projects to file in PDF format information for verification and assure electronically archiving.

The **new application** administrated by Managing Authorities and Intermediate Bodies in Romania, MySMIS 2014 version 1.0 is available from March 2016 and is used for submission of grant applications based on electronically signed documents. Other system used in parallel for reimbursement claims is Action Web: a system were the implementation documents are uploaded by the beneficiaries and partners, in PDF format, in order to be verified and archived for reimbursements of the sums to the beneficiaries.

According to *Helpdesk MySMIS (2014)* "by implementing application MySMIS 2014 European Funds Ministry responds to the regulations applicable for European programming period 2014-2020" is presented in one of the press releases of the European Funds Ministry.

The auditors and those who ensure the verification often are using a large quantity of financial information and are in position to manage with difficulty these data volumes available in electronic format in the information system in which they were originally inputted and respectively introduced into Action Web the final system (in PDF file assumed).

During the implementation of projects financed with structural funds 2007-2013 **legislation on financial auditing of projects has changed**. If initial financial audit of EU funded projects were performed without additional training for auditors in the financial funds and ended with a report of findings of fact as ISRS 4400, currently auditing activity ends with an audit report expressing an audit opinion based upon ISA 805. Furthermore since January 2014 members of the Chamber of Financial Auditors Romania must follow a training course to be enrolled in the Official Monitor of Romania as part of auditors who can perform audits of projects financed with EU funds and other grants.

The opinion based upon ISA 100-805 is necessary in order to provide to the Managing Authorities and Intermediate Bodies if the expenses are eligible.

According to *Serban* (2014), important differences between the two type of regulation used before and after the moment 2014 is related to the:

- *Independency of the auditor, according to application of ISA 200 is mandatory but according to ISRS 4400 is not;*
- *Testing of the internal control system and evaluate the fraud risks by the auditor, according to application of ISA 240 auditor must treat the fraud risks but the beneficiary is responsible for the functioning of accounting and internal control and for the ISRS the testing was optional;*

- *The use of materiality in mission done according ISA 805 and 100% sample according ISRS 4400 and this difference is very important in the way of how the mission is done respectively how can be used a software for automatic verification and issuing of reports with results according to the ISA requirements;*
- *The assurance is not absolute but is high if it is used the ISA and is not assured in the case of using ISRS 4400.*

According to Conceptual map of the Continuous Audit system based on Continuous Monitoring System Shin, Lee, Park (2013) there are three types of actions interconnected respectively: one referring to collection of data for ERP, the second regarding continuous monitoring system and third focusing in increasing effectiveness of audit process through assessing high-risk audit items.

Continuous monitoring system is represented by dash boarding exceptions of each process, monitoring exceptional data and notification management.

Conceptual map of the Continuous Audit system based on Continuous Monitoring System is applicable to European funded projects where internal audit function is not always present in the team of the project (and is not performing the audit mission for the project EU funded), so the internal control function is the interface and connection with the external audit function. According to this map first step is to determine the direction of the audit mission, in this case of audit report for the reimbursement claim.
In this case the procedures of audit will take into consideration specific legislation for European Union and will be led by the partner of the company or head of internal audit from the institutions using information from the management of the project and previous experiences of the previous years (2007-2015) in auditing EU funded projects and accounting projects of the company.

For the quality of the mission is important to have a strategy so our study is using interviews about the process of audit of EU funded projects in order to stress the practical factors that are favorable in applying continuous audit in this case.

Below we are presenting the Summary of answers received from the interviewees at some of the questions establishing the sample characteristics of interviewees.

Organisation	Position in the firm	Years of experience in audit	Prioritary clients in	Your customers average net turnover in Euro	Usage of audit software in firm	Usage of audit software for continous auditing missions	Research questions
Company organized at the county level	Partner auditor	11-15	Private sector	>700.000	Yes	Time Audit and Working Papers by Caseware	12
Company organized at the country level	Auditor	5-10	Other (except private, public and NGO's)	50.000-500.000	No	-	12
Company organized in the capital	Senior auditor	11-15	Private sector	50.000-500.000	No	-	12
Company organized in the capital	Audit manager	11-15	Public and private sectors	>700.000	Yes	Excel	12
Company organized at the country level	Audit manager	<1	Private sector	<50.000	No	-	12
Company organized at the country level	Internal Auditor	5-10	Private sector	-	Yes	Excel	12
Independent	Auditor	2-5	GO's and NGO's	50.000-500.000	Yes	Excel	12
Public institution	Internal Auditor	5-10	Public and private sectors	-	Yes	Excel	12
Company organized in the capital	Partner auditor	2-5	GO's and NGO's	50.000-500.000	Yes	Excel	12
Company organized in the capital	Audit manager	11-16	Private sector	50.000-500.000	Yes	Ciel Audit and Revision	12

Fig. 3: Summary of sample characteristics of interviewees

As a partner of an audit firm stated in our study, they are in a process of accessing electronic information from their customers in order to facilitate continuous audit missions. The same partner mentioned that the assurance of an opinion according to specific legislation for 6 to 12 months (because the project is implemented for a short period) or at every 3-6 months (for projects implemented on a period bigger than 1 year), are reasons in using software tools for continuous auditing.

Another independent auditor mentioned that the new requirement regarding the use of ISA standards is also a reason in using audit software in audit missions for EU funded projects.

Other interviewees mentioned that even until now do not have a software to receive electronic files signed electronically and input them for testing in their audit software they are interested in doing so. Another factor in using this type of missions is the fact that the majority of the EU funded projects are using the same accounting transactions during the implementation: transactions related to Staff Costs, Staff Travel, Office Costs, Transportation Costs, Allowances and Information Campaign Costs.

Other specialist underlined that the error rate issued after continuous auditing can be used without furthermore calculate it.

Questions to ask:

1 How many years of experience in audit do you have?
2 What is your position in the company / your office of audit?
3 What is the administrative representation of your audit company?
4 What kind of ownership are your clients from?
5 Do you perform audits of EU funds projects?
6 In which interval your customer's average net turnover in Euro, is situated?
7 Within your audit company (audit activities) do you use audit software?
8 What kind of audit software do you use in order to achieve a continuous audit?
9 How the continuous audit can be implemented in audits of EU funded projects?
10 Have you formalize at your company the audit process in order to have an automatic one?
11 What can motivate you to adopt continuous auditing technologies?
12 What was the impact in applying continuous auditing technologies in EU funded projects?

Fig. 4: Questions in the interview

One of the main concerns for auditors seems to be the importance of testing the application controls because of supplementary effort and expertise involved in the process.

Another auditor presented what brought to his firm the use of specialized software: more data examined, release the time pressure for auditors, better information, an automatic archived electronically history for the next audit mission.

A respondent mentioned that a young colleague is very interested in using software because of his skills in the domain and is testing one audit application available in Romanian software market.
The underline benefits of using software in audit of EU funded projects mentioned in our study:

- Secure data;
- Controlled data;
- Managed data not at the disposability of a person;
- Logged data;
- Easley reported data;
- Assurance of user and password access;
- Avert and investigation of exceptions according to Rikhardsson and Dull (2016).

Some of the limits presented in the investigation are:

- To ensure the management of exceptions;
- To deal with false positives;
- The process of follow up of the results;
- The persons involved in the process must have the correct training;
- IT personnel must be involved added by Verver (2008);
- Privacy and security threats according to Chiu, Liu, Miklos, Vasarehelyi (2014);
- Deficit of critical consideration mentioned to Rikhardsson and Dull (2016)

Conclusions and limits to the study

The study is revealing the incursion in practical processes of continuous auditing in the context of auditing EU funded projects.
Technological evolution is affecting the process and profession such as accounting and auditors according to AICPA (1998).

Our study is part of a second and third method of analysis used in general by researchers in this domain (the empirical survey and case study) as the study demonstrated by Chiu, Liu, Miklos, Vasarehelyi (2014).

As Maia Farkas, Uday S. Murthy (2013) argued, the costs of implementing continuing monitoring or auditing is in some practical cases considered to exceed the advantages.

In the Romanian case for the EU funded projects it is now a new application used in continuing monitoring of this specifically regulated field and is important to find a way of using efficiently this electronically stored data.

The Public Company Accounting Oversight Board considered that the changing of standards often can lead of using unnecessary technique sampling and that in some cases new standards must be accompanied with some changes in the techniques. As EU funded projects are specifically regulated in Romania, some practitioners tend to reveal need of techniques in order not to register over time in missions and not to perform irrelevant tasks for presenting quickly a correct audit report with a viable opinion.

According to this matter AICPA studied the steps that can be used for solving the concern of testing the application control: 1.defining the file using the technical specification; 2. defining the fields of the files; 3.usage of data validation and supplementary understanding of the completeness of data. A standardization of the file format is the next step in the process in order for it to become more efficient.

John Verver, vice-president of ACL presented (2014) an interview that all Big 4 are having projects regarding the use of technology in their activities.

Our study is limited by the relatively small number of interviewed and the type of investigation and to a relatively small number of studies related to the methodology used in continuous audit mission.
Further practical experience can bring more results related with a case where this type of missions could increase the efficiency, effectiveness and quality.

Food quality perception in the Czech Republic: trial study results

Alexandr Asmalovskij, University of Economics, Prague, Czech Republic, alexander.asmalovskij@vse.cz
Tomáš Sadílek, University of Economics, Prague, Czech Republic, tomas.sadilek@vse.cz

Abstract

The article presents outputs of trial study which discovered consumers´ opinions about food quality labels in the Czech Republic and the influence of food quality labels to shopping behaviour of foodstuff. Questionnaire research is a basis for further research, which is realized in 2016. In the paper are described theoretical foundations of food quality labels and an overview of quality labels used in the Czech foodstuff market. Within research outputs are presented sample structure, order of factors, which influence customers´ shopping behaviour the most and customers´ opinions of foodstuffs labelled by quality labels.

Keywords: food quality labels, shopping behaviour, consumers´ opinion

Introduction

After lifting food quality standards in 1993, quality of numerous products has decreased without attention on the side of the consumers. Gradually, information began appearing that it is necessary to monitor composition of products as they actually might not contain the ingredients they should. The problem was and still remains that in the process of shopping consumers do not want to spend time reading unclear and often confusing information on composition of the products which is usually even missing at over-the-counter sale. Therefore, it is common that consumers purchase spurious products where name and packaging play the key role, not the actual composition or nutritional value.

Over time, price has become guidance for quality of food products. But nowadays even that is no guarantee for quality or content of the ingredients expected by the consumers. On the one hand, some product quality indicators are improving, on the other hand, use of substitutes in foodstuffs is growing. Quality labels the number of which is growing rapidly on the market are supposed to resolve the issue. These labels should guarantee quality of products in terms of composition, place, or method of production, and should help consumers choose fine quality, unadulterated food.

Due to the fact that quality is gradually becoming a significant factor in the choice of food by more and more consumers, quality labels are gaining importance as well. They are substantial not only for consumers but also manufacturers who are able to attract attention or differentiate from the competition thanks to products which meet the parameters for obtaining such label of quality.

Theoretical Background

Quality labels, or the so called utility signs, are graphic symbols that appear on a product, its packaging, or enclosed information materials. They inform about particular parameters of a product (packaging), or its use (Velčovská, 2005).
They are a tool to reassure consumers about the quality through certification. Specific labels only cover certain aspects of quality. It means that the market offers product or service quality labels.
According to Tulder (2006) there is great diversity within quality labels. Symbols are divided into several categories which may overlap with one another. Those are related to:
- Industry (sector) - e.g. HORECA Select,
- Working conditions - e.g. Fairtrade, Oké bananas,
- Production conditions - e.g. FSC certification, Rainforest Alliance,
- Recycling and organic products - e.g. Eco-O.K.,
- HR policies - e.g. Investor in People,
- Product - e.g. Klasa.

All utility signs are segmented in higher detail by Velčovská (2005) according to the following criteria: in terms of severity, content, extent, and geographic perspective.

There is no doubt that quality labels have undeniable importance for producers as well as consumers. To consumers they provide certain assurance as products marked by such labels must meet the established standards and requirements. They also contribute to simpler orientation on the market and help choose a quality product or service with minimal risk. Currently, one of the assumptions about todays´ consumer behaviour is the fact that people are increasingly buying products not because of their parameters but for the personal value they represent. Products are often evaluated according to their specific qualities (not the main benefit it should deliver), but the so called enhanced product (a set of intangible elements which bring the perceived advantage to the consumer, e.g. image, service, consulting, etc.). Quality labels are part of the enhanced product which influences consumer behaviour. (Turčínková, 2007; Klánová, 2013)

Contribution of brands for manufacturers is often far greater than benefits for consumers. Quality labels can serve as an effective marketing tool which leads to an increase in sales (after being marked with a brand logo) and raise in awareness among consumers. Brands are therefore considered an important tool for manufacturer´s sales support. The survey conducted by Focus Agency for an expert periodical Marketing Journal shows that 81% of companies see the main benefits of using quality labels in the expected increase in consumer confidence. Another benefit is the aforementioned increase in revenues and a way to differentiate from competition. Also, 39% of companies perceive quality labels as a guarantee of production stability and high quality of its products. (Focus Agency, 2013; Horacek, 2014)

Czech food market is flooded by a large number of quality labels which should function as a guide for consumers and at the same time guarantee quality and origin of products. Consumers may encounter labels used exclusively for food products (eg. Klasa or Regionální potravina), or labels given in other product categories (eg. CZECH MADE or Český výrobek).

Table 1: Quality labels used in the Czech Republic

Logo	Name	Characteristics
	KLASA	Label awarded by the Ministry of Agriculture to food and agricultural products of finest quality.
	Český výrobek – guaranteed by Federation of the Food & Drink Industries of the Czech Republic	Products must be manufactured in the Czech Republic and must contain a certain share of Czech ingredients. The label is awarded by Federation of the Food & Drink Industries of the Czech Republic.
	Český výrobek (belongs to the Český výrobek fund)	Label for both food and non-food products whose production company is owned by Czech citizens and revenue is not transferred outside the country. Label is awarded by Český výrobek fund.

	Český výrobek (belongs to Český výrobek Ltd.)	Designation of safe products manufactured in the Czech Republic (where employees are Czech). The label is granted by Český výrobek Ltd.
	Czech made	The label which is part of the state program Česká kvalita reflects that the quality of designated goods and services has been objectively verified by a third party. This label is awarded by Sdružení pro Cenu České republiky za jakost.
	BIO – a product of eco agriculture	Nationwide trademark for organic food given awarded by organizations entrusted by the Ministry of Agriculture.
	BIO in EU	EU logo for organic packaged foods, which was introduced by the European Commission.
	Ekologicky šetrný výrobek (Eco-friendly product)	Goods and services that are proven environmentally and consumer health friendly, label is granted by the Ministry of the Environment.
	Regionální potravina (Reginal food)	Label awarded by the Ministry of Agriculture to finest-quality agricultural products that win in regional competitions.
	Vím, co jím (I know what I eat)	Designation of nutritionally balanced food granted by the non-profit organization Vím, co jím a piju.

	Zdravá potravina (Healthy food)	Labelled food must not contain controversial additives, artificial flavourings and E-additives, is awarded by Zdravá potravina.
	Certified e-friedly food (CEFF)	Food products without preservatives, artificial colourings and flavours, the label is awarded by an independent institution.
	Chráněné zeměpisné označení (Protected geographic trademark)	Designation of an exceptional agricultural product or foodstuff from a given region / location. At least one phase of production - production, processing, or preparation must take place in the designated area. Awarded by the European Commission.
	Chráněné označení původu (Protected origin trademark)	Designation of an exceptional agricultural product or foodstuff from a given region / location. All stages of production must take place in the designated area, it also applies to ingredients. Awarded by the European Commission.
	Zaručená tradiční specialita (Guaranteed traditional specialty)	Agricultural product or foodstuff produced or manufactured for at least 30 years specific nature of which is recognized by the EU. Awarded by the European Commission.
	Fair Trade	A certification system for products from the countries of the Third World where consumer buying this product helps disadvantaged producers (mainly from the Third World countries). Managed by Fairtrade Labelling Organisation International.

Methodology

This paper aims to (1) identify the main factors in decision-making while purchasing food and their order stated by the respondents, (2) discover knowledge and recognition of quality labels that appear on the Czech food market, and (3) gain respondents´ opinions on food products marked by quality labels.

The presented study is a trial for the research on quality labels. In the trial during the period from December 2015 to January 2016, 36 respondents were interviewed distribution whom roughly corresponds the distribution of the monitored categories of the population sample. The survey sample consisted of residents of the Czech Republic over 18 years of age addressed in front of grocery stores. The interviews were recorded for qualitative evaluation. Based on the information obtained from the trial study, the questionnaire will be adjusted for final interviews.

The research technique used were individual semi-structured interviews, the respondents answered a set of 13 questions with closed and open-ended answers and scales. Representative technique was used for the selection of respondents, namely simple random selection where respondents were interviewed in front of grocery stores. The questions were focused on the attitude of respondents towards purchasing food labelled by quality labels and their knowledge of quality labels placed on food sold in the Czech Republic. Further segmentation questionnaire contained questions on household size, total net income of the respondent´s household, the highest educational attainment of the respondent, and zip code for region identification. The aim of the survey was to get the majority of responses from women who have higher influence on shopping behaviour of food and stronger decision-making power than men. The respondents were willing to answer questions, and no significant number of respondents who would be reluctant to participate in the questioning was registered. The obtained data were then processed and classification of the first and second degree was conducted, followed by correlation analysis and hypotheses testing.

Research Results

Responses were distributed evenly within the sample according to the number of members in the households, as well as in the category of total monthly net income of the households. In the category of gender, a higher proportion of women was reached, which is advantageous as in most families women take decisions on food purchase. Unequal representation was achieved in the category of age where almost over 41% of respondents fall into the age group of 20-29 years. The territorial distribution of the respondents is that nearly 64% of respondents come from the Central Bohemian Region, the rest of the respondents from the regions of Olomouc and Plzen. Thus it is possible to say that the inquirers managed to ensure representation of respondents living in large cities and near such cities who usually have different lifestyle and therefore distinct shopping behaviour from people living in rural areas.

Table 2: Sample characteristics

Number of household members	1	8,3 %	**Total monthly net income of households**	up to 10 000 CZK	16,7 %
	2	22,3 %		10 000 – 20 000 CZK	19,4 %
	3	22,2 %		20 000 – 30 000 CZK	27,8 %
	4	22,2 %		30 000 – 40 000 CZK	13,9 %
	5	25 %		40 000 – 60 000	11,1 %

				CZK	
				over 60 000 CZK	11,1 %
Education	Primary	11,1 %	**Age**	20 -29 years	41,7 %
	Secondary	16,7 %		30 – 39 years	19,5%
	Secondary (higher)	44,4 %		40 – 49 years	19,4 %
	College	2,8 %		50 – 59 years	11,1 %
	University	25,0 %		60 years and more	8,3 %
Gender	Female	63,9 %	**Region**	Central Bohemian	63,8 %
	Male	36,1 %		Plzen	2,8 %
				Olomouc	33,4 %

In the ranking of the factors that most affect food purchase, an earlier assumption was confirmed that price is the main criterion. Each respondent was asked to state three factors that most influence their purchase of food and, in addition to price, respondents placed great emphasis on the origin of products (whether it is a Czech or foreign products and whether it is a regional product, or a product imported from a greater distance). Among other qualities, appearance of the product was considered important. Other factors that placed on the first to fifth position were quality, composition of the product, taste (which is the most subjective criterion), and recommendation. Quality label placed 7th in case of the first factor, 10th as the second factor, and 3rd in stating the third factor. This means that quality label is not one of the main selection criteria for the respondents.

Table 3: Order of factors with most influence on food purchase

	First factor	**Second factor**	**Third factor**
1	Price	Price	Price
2	Origin	Origin	Appearance
3	Quality	Composition	**Quality label**
4	Composition	Appearance	Composition
5	Taste	Other	Recommendation
6	Appearance	Recommendation	Quality
7	**Quality label**	Habit	Freshness
8	Habit	Freshness	Taste
9	Freshness	Taste	Shelf-life
10	Other	**Quality label**	Appearance

The tests made on rank correlation (Kendall's tau) did not confirm dependency between the order of the factors cited meaning that it is impossible to say unequivocally which factor respondents generally consider as the most important as there is no trend of a single factor appearing on the first place. Values of Kendall's tau varied from -0.433 to 0.06 and are statistically significant at a significance level of $\alpha = 0.05$.

Like in the previous question on factors influencing food purchases, respondents were asked to name three quality labels they know. This confirmed the earlier assumption that Klasa holds the leading position on the Czech food market as the majority of respondents named it as the first option. Many respondents were not able to name a second label, however, Český produkt, Bio, and the response "Other" appeared among the answers. The respondents also named brands that do not belong among quality labels – e.g. private labels of retail chains. Therefore it is possible to conclude that the concept of quality labels is unclear for many respondents and, despite repeated campaigns to promote recognition and knowledge of quality labels, consumers are still unsure about what such labels represent in detail. More precisely, shoppers understand that a quality label represents higher quality standard compared to other unmarked goods, but they lack certain knowledge on what particular production standards, ingredients, or other norms a label stands for or should inform about. As the second option, respondents named Český produkt, Regionální potravina, and Zdravá potravina. It is also interesting that some reported Chráněné zeměpisné označení a Chráněné označení původu as the second and third answer since those labels are not often known among Czech consumers.

Table 4: Order of labels by awareness

	First label	**Second label**	**Third label**
1	Klasa	Other	Regionální potravina
2	Český produkt	Český výrobek	Other
3	Other	Chráněné zeměpisné označení	Chráněné označení původu
4	Bio	Regionální potravina	Český produkt
5		Český produkt	
6		Zdravá potravina	

Even in this case the conducted rank correlation tests (Kendall's tau) did not confirm any dependency between awareness rankings of quality labels, which means that it is not possible to say unequivocally which labels are more significant than others, except for the Klasa label whose position is exceptional. Values of Kendall's tau vary from -0.501 to 0.229 and are statistically significant at a significance level of $\alpha = 0.05$, at the same time there is no visible trend.

Another aim of this paper was to find out opinions of the respondents on food products marked with quality labels. It is noteworthy that 94.4% of respondents rather agree that labelled foodstuffs meet their expectations, but only 58.3% of respondents consider these products actually better (13.9% absolutely agree and 44.4% rather agree) while 30.6% of respondents were neither concurring nor dissenting. Similarly, the respondents answered questions on whether the labelled products are trustworthy where 61.1% of respondents agree with such statement (19.4% absolutely agree and 41.7% rather agree), which may seem interesting for food producers who endeavour to obtain some of the quality labels. Willingness to pay extra money for the labelled food products was confirmed by 72.2% of the respondents which shows a positive trend that consumers are willing to pay more for products which are marked with quality labels and which are expected to have higher quality than unlabelled products. These findings may also be confirmed by one-sample t-test the value of which reached $t = 0$ at a significance level of $\alpha = 0.05$. Such fact may look slightly paradox as from the aforementioned test of stating three most influential factors and naming three quality labels it seems

that most consumers do not have detailed knowledge on particular standards represented by each quality label.

Table 5: Respondents' opinion on labelled food products

	1	2	3	4	5	T-test value
Do food products marked with quality labels meet your expectations?	0	94,4	5,6	0	0	Sig = 0, T = 53,09
In your opinion, are labelled food products of better quality?	13,9	44,4	30,6	2,8	2,8	Sig = 0, T = 15,43
In your opinion, are quality labels trustworthy?	19,4	41,7	22,2	8,3	2,8	Sig = 0, T = 13,36
Are you willing to pay more for labelled than unlabelled products?	27,8	44,4	13,9	5,6	2,8	Sig = 0, T= 12,21

Note: 1 – absolutely agree, 2 – rather agree, 3 – neither agree nor disagree, 4 – rather disagree, 5 – absolutely disagree

Conclusion

Based on the trial of quality labels where 36 respondents were interviewed several conclusions can be drawn. In identifying three factors that most affect consumers while shopping food, an aforementioned assumption was confirmed that the most important factor is price. However, the assumption cannot be unequivocally confirmed at this stage of the research. More accurate results will appear with a higher number of respondents and statistically significant correlation. In the opinion of consumers, the second most important factor after price is origin of the food, where in addition respondents care what country a product comes from and, in case it is a domestic product, from which region. The third most influential factor according to the gathered information is appearance of products. Visual characteristics therefore play an important role in food selection. It is also necessary to mention other factors which occurred on various positions from first to fifth, those are: quality, composition of the product, taste, and word of mouth or recommendation. Based on all the previously mentioned information it is possible to conclude that quality labels are not one of the key factors in food selection and thus do not have significant influence on consumer behaviour.

Respondents were also asked to name three labels of quality, most frequently they named Klasa as the first option. Based on the results of this study, Klasa seems to have the highest awareness on the Czech market. Other labels featured on the first place are Český výrobek and Bio. In addition, respondents also named brands which are not considered quality labels but private labels of retail chains. Several respondents were unable to name any brand of quality. These facts reveal that brand awareness of quality labels in the Czech Republic is generally not high. Such labelling thus has low significance and consumers do not have an entirely clear and accurate idea of what quality labels mean. They have a general idea that labelled products should have higher quality, but mostly do not have particular knowledge on what exactly each label represents in terms of production standards, norms, origin or ingredient requirements. One of the reasons for this could be that there are too many quality labels on the Czech food market, which can cause confusion in consumers´ perception of food quality labels. Another reason can be the influence of price on consumers´ decision making as for many shoppers in the Czech Republic, price is the most important criterion in the process of purchasing food.

The final part of the study examined consumers´ views on food products marked with quality labels. Nearly 95% of the respondents rather agree that labelled foodstuffs meet their expectations, while only 58% of consumers actually consider labelled products to have higher quality in comparison with

conventional products. As for the question whether quality labels are trustworthy, 61% of those surveyed responded approvingly, while 19% absolutely agree and 42% rather agree with this statement. At the same time, 72% of the respondents are willing to pay more for the labelled food products than for those unlabelled, simply because they view labelled foodstuffs as products with higher quality or some exceptional value, or in case of Bio label they can expect products to be healthier. In conclusion, approximately two thirds of consumers trust quality labels and almost three quarters are willing to pay extra money for such labelled products. However, as a matter of fact but somewhat paradoxically, the awareness of these labels and knowledge about their particular meaning is not high. Therefore, the question remains whether and what actual value labels of quality have on the food market in the Czech Republic.

Acknowledgment

The research was supported by grant F2/94/2015 Analysis of quality labels utilization in the Czech food market and efficiency of campaigns supporting them of Faculty of International Relations, University of Economics, Prague.

Abstract

This study examines the degree of financial misreporting through real earnings management practices of Government Linked Companies (GLCs) listed on Bursa Malaysia. In addition, this study investigates the impact of total government shareholdings on real earnings management. Consistent with prior research, this study uses three proxies to measure real earnings management; abnormal cash flow from operations, abnormal production costs and abnormal discretionary expenses. Using a sample of 329 firm-year observations from 2001 to 2014, this study finds that government ownership has significantly negative association with all proxies of real earnings management. Overall, the results suggest that government ownership as an effective monitoring mechanism in limiting real earnings management practices. The findings support the incentive alignment hypothesis which argues that companies with government intervention are normally better governed.

Keywords— *government ownership, government linked companies, real earnings management*

1.0 Introduction

Prior studies highlight that government ownership affect earnings management activities (Ding, Zhang & Zhang, 2007; Har, Majdi & Mohammed, 2012; Jamaludin, Mohd-Sanusi & Kamaluddin, 2015; Jow, Loo, Zainal-Abidin, Noordin & Ariffin, 2007). In general, there are two competing views on the effects of government intervention on companies' earnings management practices. According to the incentive alignment argument, companies with government intervention are normally are better governed (Ang & Ding, 2006; Lau & Tong, 2008) and more politically sensitive (Mohd Ghazali, 2007). More specifically, the activities of these firms are not only under the watchful eyes of the public, i.e., the investors and shareholders, but also the government. As a result, management of these firms is more conscious of the importance of maximising shareholders' value over self-interest, which might limit managerial opportunism (Lau & Tong, 2008).

On the other hand, Wang (2002) contends that government intervention is the main factor for the inefficiency of state shareholdings, resulting from poor governance practices and greater agency problems. Ding et al. (2007) argue that the agency problems in state-owned firms are more complex than in privately-owned firms because there is an extra agency relationship in such firms as the controlling owners are themselves agents of the true owners i.e., the state. In particular, there is one more type of agency cost in state-owned firms—the agency cost between the state and the controlling owner—in addition to the agency cost between the controlling owner and minority shareholders. Further, Jow et al. (2007) argue that unlike owner-managers who have to risk their own resources, GLCs managers are using public funds as their major resources. The nature of their compensation, which is directly tied to accounting number, creates more incentive for the top management to

manage the reported earnings in order to maximise their compensation. Consistent with these conflicting theories, previous research on the relationship between government ownership and earnings management provided mixed results (see for example Jow et al, 2007; Hoang et al., 2014; Chen et al., 2003; Wang & Yung, 2011; Har et al, 2012).

In addition, in spite of growing research on earnings management of GLCs, most of the research uses accrual-based measures as key proxies of earnings management. According to Graham, Harvey and Rajgopal (2005) managers prefer real activities manipulation to accrual earnings management. Given that, this paper attempts to extend prior studies by examining the degree of REM practices and the specific factors that affect managerial decisions to manage earnings in GLC of Malaysian capital market.

This study uses Malaysia as a research setting due to several reasons. First, government ownership is strong feature of the Malaysian corporate sector. According to Jow et al. (2007), GLCs represent approximately 40 per cent of the market capitalisation of the Malaysian stock market. Second, in Malaysia, GLCs play an important role in the development of the economy as their main objectives are not purely profit driven but are to achieve social objectives. GLCs have special advantages to access to government's funds, tenders and opportunities. Given such important roles play by GLCs and its special advantages, Hawani et al. (2011) argue that GLCs have responsibility to share the government responsibility in discharging their public accountability by leading other companies by having good corporate practices and producing high quality of reported earnings.

Using 329 firm-year observations from 2001 to 2014, we find that GLC have significantly negative abnormal cash flow from operations, abnormal production costs and abnormal discretionary expenses. The findings suggest that when the Malaysian listed firms have government ownership more than 10 percent of total shareholding, the level of real earnings management activities will be reduced.

This paper has multifaceted contributions. First, the study expands on the existing body of knowledge on the relation between government ownership and the level of earnings management. This is an extension of prior studies on government ownership influence on accrual earnings management (Har et al., 2012; Jamaludin et al., 2015; Jow et al., 2007) by examining the impact of government ownership on another perspective of earnings management activities; real earnings management. Second, from a regulatory perspective, the paper shows that government ownership can help to promote confidence in the quality and reliability of audited financial statements in Malaysia setting.

The remainder of the paper is organized as follows. Section two provide a brief description of Malaysian GLC. Section three draws a connection between earnings management and government ownership and develops the research hypothesis. Section four elaborates the research design. Section five presents and discusses the findings. The final section provides the summary and conclusions.

2.0 Institutional Background

2.1 Malaysian Government Linked Companies

In Malaysia, GLCs play an important role in the development of the economy as their main objectives are not purely profit driven but are to achieve social objectives. In particular, GLCs have been set up to restructure and ensure a more equitable society by enhancing Bumiputera participation in the corporate sector and the Malaysian capital market. GLCs are controlled by the Malaysian government through Government-linked Investment Companies (GLICs). GLICs are the investment arms of the government allocating some or all their funds to GLC investments. Currently, there are seven GLICs including: the Employee Provident Fund, Khazanah Nasional Berhad, Kumpulan Wang Amanah Pencen, Lembaga Tabung Angkatan Tentera, Lembaga Tabung Haji, Menteri Kewangan Diperbadankan and Permodalan Nasional Berhad. Apart from having controlling ownership in the GLCs, the government also has the ability to appoint board members, senior management and make

major decisions in such areas as contract awards, strategy, restructuring and financing, acquisitions and divestment for GLCs.

Nonetheless, Malaysian GLCs have been subject to criticism as poor performance firms. In response, Malaysian government in 2004 has embarked transformation initiative in restructuring GLCs to become more commercial in nature, despite their social and national obligations. The transformation has been monitored by government agency known as Putrajaya Committee on GLC (PCG). The transformation policy highlights ten initiatives; (1) enhance board effectiveness; (2) strengthen directors' capabilities; (3) enhance GLICs monitoring and managerial functions; (4) improve regulatory improvement; (5) clarify social obligations; (6) review and revamp procurement; (7) optimize capital management practices; (8) manage and develop leaders and other human capital; (9) intensify performance and management practices; and (10) enhance operational improvement.

In a nutshell, as the transformation program emphasize on the effectiveness of corporate governance of the GLCs through certain board characteristics such as board size, board meetings, multiple directorships, it is expected that the GLCs are less likely to be involved in earnings management including real manipulation activities.

3.0 Literature Review

3.1 Earnings Management and Government Ownership

Healy and Wahlen (1999) defined earnings management as an opportunistic behaviour. It occurs when managers use judgment in financial reporting to alter accounting number to either mislead some stakeholders about the underlying economic performance of the company or to influence contractual outcomes. According to Fields, Lys and Vincent (2001), managers can influence reported accounting numbers by managing accounting choices either via accrual (hereafter referred to as accrual earnings management (AAC)) or real-based transactions (hereafter referred to as real earnings management (REM)). The former refers to the earnings management activities that have no direct cash flow implications. For example decision to write down assets, to recognize or defer revenues, to capitalize or expense certain costs such as repair expenditures, and timing of adoption of new standards. REM occurs when manager use real economic actions that affect cash flows to produce a desired earnings (Dechow and Schrand, 2004, Fields, Lys and Vincent, 2001). Examples of REM include reductions in discretionary spending such as research and development (R&D), advertising and maintenance expenditures, aggressive price discounts to increase sales volumes, overproduction to report lower cost of goods sold (COGS) and repurchase common share.

A review of literature on the impact of government ownership on opportunistic earnings management documented mixed empirical results. For example, consistent with the management entrenchment effect hypothesis, Chen et al. (2003) find that local government has a significant positive relationship with earnings management practices of listed firms located in their jurisdiction in order to meet the regulation stipulated by the central government. Further, Ding et al. (2007) examine earnings management practices in Chinese state-owned listed firms. This study revealed that such firms are more likely to manage earnings via operating-related accrual mechanisms and non-operating transactions with related parties.

Ben-Nasr et al. (2015) examine whether state ownership affect earnings quality. They hypothesize that government has more incentives to tunnel corporate resources and expropriate other shareholders for political benefits. To hide this expropriation, the government may lead managers to manipulate earnings, which results in a lower quality of accounting earnings. Using 350 firms from 45 countries, they find that state ownership is associated with greater abnormal accruals, lower earnings informativeness and more transitory earnings. The results indicate that state ownership is associated with lower earnings quality than their counterparts.

Nevertheless, some scholars cast doubt on entrenchment effect of government ownership on opportunistic earnings management (Hoang et al., 2014; Wang & Yung, 2011; Jow et al., 2007). For

example, Wang and Yung (2011) examine the impact of state ownership on earnings management in China. The results show that state owned firms have lower levels of earnings management than privately owned firms. This indicates that government play an important role in mitigating the management's pressure to manipulate earnings numbers.

In a related study but using Vietnamese data, the work carried out by Hoang et al. (2014) who investigates the impact of state ownership on earnings management of listed firms on Ho Chi Minh Stock Exchange and Hanoi Stock Exchange. The findings suggest that state ownership limit opportunistic earnings management by accrual accounting choices.

In the Malaysian context, Jow et al. (2007) investigate the prevalence of earnings management between GLCs and Chinese family-linked companies. They argue that the motive of GLCs to manage reported earnings is related to managerial compensation plans as their managers' compensation is tied directly to accounting results. On the other hand, the motive of Chinese family-linked firms to engage in income-decreasing earnings management might be attributed to tax related issues as management attempt to minimise taxable income, and improve cash flows. However, the results show that there is a negative relationship between concentration of shareholdings and earnings management in GLCs. This indicates that GLCs are less likely to manage earnings numbers via abnormal accruals. Recently, Har et al. (2012) investigate the impact of the transformation policy on the degree of earnings management of GLC. In particular, this study attempted to examine the association between the board characteristics and the earnings management of the listed GLCs in Malaysia. The findings reveal that there is an increase of earnings management activities in the post-transformation policy. In addition the results also show that none of the board characteristics limit opportunistic earnings management except for board meeting and CEO duality.

Despite mixed results on the relationship between government ownership and earnings management, GLCs transformation program which emphasis on the effectiveness of corporate governance mechanisms are expected to deter earnings management practices. Based on this notion, this study hypothesises that:

H_1: Government Linked Companies have lower level of real-based earnings management.

4.0 Research Design and Methodology

4.1 Sample Selection and Data Collection

The sample for this study covers GLCs listed on Bursa Malaysia from 2001 to 2014. Data required for computing earnings management and control variables measures are collected from Thompson Reuters Datastream. Other non-financial data were collected from the companies' annual reports. We exclude GLCs in the banking and finance sector because they have different guidelines and governance systems (Abdul Rahman and Mohamed Ali, 2006). We also exclude firm-year observations with missing earnings management measures data. This procedure yields 329 firm-year observations.

4.2 Operationalisation of the Dependent, Independent and Control Variables

4.2.1 Dependent Variables:

4.2.1.1 Real Earnings Management

Following to Roychowdhury (2006) and Cohen and Zarowin (2010), this study refers real earnings management as actions managers take that deviate from normal business practices. Consistent with prior research (Roychowdhury, 2006; Cohen & Zarowin, 2010), this study employed three metrics to examine real earnings management, namely the abnormal levels of cash flow from operations (RCFO), abnormal production costs (RPC) and abnormal discretionary expenses (RDE).

Consistent to Roychowdhury (2006), the study estimates RCFO, RPC and RDE as the residual from the following model respectively.

$$CFO_{it}/A_{it-1} = \beta_1 [1/A_{it-1}] + \beta_2[Sales_{it} / A_{it-1}] + \beta_3[\Lambda Sales_{it} / A_{it-1}] + \varepsilon_{it}$$

Where,

CFO_{it}	Cash flow from operation in period t
A_{it-1}	Total assets of firm i in year t-1;
$Sales_{it}$	Sales of firm i in year t
$\Lambda Sales_{it}$	Sales of firm i in year t less revenues of firm i in year t-1;
ε_{it}	A residual term that captures the level of abnormal cash flow of firm i in year t.

$$PROD_{it}/A_{it-1} = \beta_1 [1/A_{it-1}] + \beta_2[Sales_{it} / A_{it-1}] + \beta_3[\Lambda Sales_{it} / A_{it-1}] + \beta_4[\Lambda Sales_{it-1} / A_{it-1}] + \varepsilon_{it}$$

Where,

$PROD_{it}$	The sum of cost of goods sold and change in inventory of firm i in year t;
ε_{it}	A residual term that captures the level of abnormal production cost of firm i in year t.

$$DISCEXP_{it}/A_{it-1} = \beta_1 [1/A_{it-1}] + \beta_2 [Sales_{it-1} / A_{it-1}] + \varepsilon_{it}$$

Where,

$DISCEXP_{it}$	The sum of R&D expenses and SG&A of firm i in year t;
ε_{it}	A residual term that captures the level of abnormal discretionary expenses of firm i in year t.

4.2.2 Independent Variable: Government Ownership

The key independent variable of the study is government ownership. The measure of government ownership is a total percentage shareholding belong to government or via its government linked investment companies such as the Employee Provident Fund, Khazanah Nasional Berhad, Kumpulan Wang Amanah Pencen, Lembaga Tabung Angkatan Tentera, Lembaga Tabung Haji, Menteri Kewangan Diperbadankan and Permodalan Nasional Berhad. The study uses the list of GLCs issued by the Putrajaya Committee to identify the GLCs status.

4.2.3 Control Variables

To test the hypothesis, this study controls for variables that could influence earnings management. These control variables are classified into two categories: firm characteristics and board characteristics.

With regards to the firm characteristics, first, the study controls for firm size. Large firms often receive more media attention, have higher analyst following and face regular political scrutiny (Ahmed & Duellman, 2007; Watt & Zimmerman, 1978). Therefore, they would tend not to manage their earnings upwards. Second, the study controls for debt. Firms with higher levels of debt would have their earnings scrutinized by debt providers or their agents, e.g., trustees, such that they do not inflate earnings to benefit the shareholders or mangers at the expense of the debt providers through dividends and earnings-based compensations (Ahmed et al., 2002). Third, the study controls for growth. Growth firms are likely to have higher accruals because of increased revenue-generating activities, such as credit sales. Fourth, the study controls for profit. Abdul Rahman and Ali (2006) note that firms with low performance (ROA) have more incentive to engage in earnings management. Fourth, the study control for audit quality. According to Wahab et al. (2007) higher quality auditors are more likely to ensure greater transparency and eliminate mistakes in financial statements since

they are more likely to protect their reputation. Therefore, we predict a negative association between audit quality and earnings management.

Following prior research, the study control for board characteristics. First, the study control for board independent. Fama and Jensen (1983) theorised that the board of directors is the highest internal control mechanism responsible for monitoring the actions of top management. However, they argue that the ability of the board to act as an effective monitoring mechanism depends on its independence from management. Independent directors are believed to be able to monitor managers as they have incentives to develop their reputations as experts in decision control (Agrawal & Chadha, 2005). Thus, the presence of independent directors on the board is seen as the check and balance mechanism in enhancing a board's effectiveness and constraining opportunistic behaviour among managers. This study predicts a negative association between board independence and earnings management practices as the theory suggests.

Secondly, the study controls for board size. Jensen (1993) and Gracia-Meca and Ballesta (2009) suggest that the number of directors is one of the important factors in the effectiveness of the board. There are two views regarding this issue. Proponents of agency theory believe that a larger board has more opportunity to control and monitor the actions of management as it has a greater number of people with more expertise (Dalton et al., 1999), and valuable experience (Xie et al., 2003) to prevent or limit managerial opportunistic behaviour. Further, Finkelstein and D'Aveni (1994) noted that a larger board has more problem-solving capabilities as the burden of the directors is equally shared among them.

Thirdly, the study controls for audit-committee independence. Prior studies suggest that the effectiveness of an audit committee is due, in part, to the extent to which the committee is independent. Indeed, a study by Peasnell et al. (2005) failed to find evidence that the existence of an audit committee reduces the level of earnings management. This result suggests that the presence of an audit committee alone, without independent members, is less likely to be an effective monitor for managerial opportunism. Independence is considered an essential quality for an audit committee in fulfilling its oversight role as it allows both the internal and external auditors to remain free of undue influences and interference from management (Vicknair, Hickman & Carnes, 1993).

Fourthly, the study controls for CEO duality. CEO duality or the 'dominant personality' phenomenon occurs when the same person holds the two most dominant posts in the firm, namely those of CEO and chairman. Advocates of agency theory argue that CEO duality—which implies CEO dominance over the board—promotes CEO entrenchment and hence, can lead to opportunistic and inefficient behaviour that reduces shareholder wealth (Jensen & Meckling, 1976).

Finally, the study controls for the Muslim chairman and Muslim board members. Bardai (2002) studied the influence of the Islamic ethical code on Muslim board members. He contends that as followers of Islam, Muslim directors believe that they are servants of Allah, who are required to serve Allah through good behaviour in all aspects of their daily life, even in their work and business dealings. They are expected to be honest, sincere, and truthful in their business dealings and transactions, and manage their business within the ethical framework devised by Allah. Year dummy and industry dummy is also included in the study to controls for the year and industry effect.

Table 4.1: Operationalisation of the Research Variables

Variables	Acronym	Operationalisation
Dependent variables:		
Abnormal Cash Flows	RCFO	Natural log of the residual of a regression (RCFO Model, Rochowdhury, 2006)
Abnormal Production Costs	RPC	Natural log of the residual of a regression (RPC Model, Rochowdhury, 2006)
Abnormal Discretionary Expenses	RDE	Natural log of the residual of a regression (RDE Model, Rochowdhury, 2006)
Independent variable:		
Government ownership	GOVOWN	Total percentage of government shareholding (10 percent and above)
Control variables:		
Board independent	BODIND	The percentage of board members who are independent non-executives directors.
Board size	BODSIZE	The number of a firm's board members.
CEO duality	DUALITY	1 if CEO and chairman of the board are same persons, 0 otherwise.
Audit committee independent	ACIND	The percentage of audit committee members who are independent non-executives directors.
Audit committee size	ACSIZE	The number of a firm's audit committee.
Muslim Chairman	MUSCH	1 if a firm's Chairman is Muslim, 0 otherwise.
Muslim CEO	MUSCEO	1 if a firm's CEO is Muslim, 0 otherwise.
Size	SIZE	Natural log of total assets.
Debt	LEVERAGE	The ratio of total liabilities to total assets.
Growth	GROWTH	The ratio of market value to book value.
Profit	PROFIT	Earnings (EBIT) to total assets.
Audit quality	BIG4	1 if a firm is audited by Big-4 audit firms, 0 otherwise.

4.4.3 Multivariate Regression Models

A multiple regression analysis was employed to test the research hypothesis. The following four multiple regressions were estimated to investigate the impact of government ownership on each proxy of real earnings management. The regression equations are as follows:

$$RCFO_{ft} = \alpha + \alpha_1 GOVOWN_{ft} + + f(control\ variables) + \xi \quad (1)$$

$$RPC_{ft} = \alpha + \alpha_1 GOVOWN_{ft} + f(control\ variables) + \xi \quad (2)$$

$$RDE_{ft} = \alpha + \alpha_1 GOVOWN_{ft} + f(control\ variables) + \xi \quad (3)$$

Where,

Dependent variable:

$RCFO_{ft}$ Natural log of absolute value of abnormal cash flows of firm *f* in year *t*,

RPC_{ft} Natural log of absolute value of abnormal production costs of firm *f* in year *t*,

RDE_{ft} Natural log of absolute value of abnormal discretionary expenses of firm *f* in year *t* computed on the basis of RDE Model (Roychowdhury, 2006),

Independent variable:

$GOVOWN_{ft}$ Total percentage of government shareholding,

Control variables:

$BODIND_{ft}$ The proportion of independent directors on the board,

$BODSIZE_{ft}$ The number of directors on the board,

$ACIND_{ft}$	The proportion of independent directors on the audit committee,
$ACSIZE_{ft}$	The number of directors on the audit committee,
$DUALITY_{ft}$	1 if CEO is board chair and 0 otherwise,
$MUSCH_{ft}$	1 if a firm's Chairman is Muslim, 0 otherwise
$MUSCEO_{ft}$	The proportion of board members who are Muslim.

IND_{ft}	Industry.

The next section reports and discusses the findings of the study.

5.0 Results and Findings

5.1 Descriptive Analysis

5.1.1 Sample characteristics

With regards to the classification of firms into respective industry groups, the largest portion of the sample is from the trading and services sector, which accounts for 44 per cent of the sample. This is followed by the industrial product sector (11 per cent), infrastructure sector (11 per cent), and plantation sector (11 per cent). Meanwhile, 5 per cent are from the technology sector, property sector and costruction. The consumer product industry makes up approximately 8 per cent of sample firms.

5.2 Descriptive Analysis

The descriptive statistics of the REM proxies use in the study are shown in Table 5.1. As shown in Table 5.1, the mean value of RCFO, RPC, and RDE are 0.60, 0.54, and .030 respectively for GLC.

Table 5.1: Descriptive Statistics of REM Measures

	Min	Max	Mean	Std Dev	Skewness	Kurtosis
RCFO	.00	0.22	.060	.07943	1.83	3.89
RPC	.00	3.19	.540	.20535	1.90	3.85
RDE	.00	0.22	.030	.21776	3.00	4.69

5.3 Correlation Analysis

Table 5.2 shows the Pearson correlations between REM measures and GOVOWN of GLC. In general, GOVOWN is negatively correlated to RCFO, RPC and RDE.

Table 5.2: Correlation analysis of REM Proxies and GOVOWN

	GOVOWN	RCFO	RPC	RDE
GOVOWN	1.00	-.086**	-.069*	-.071**
RCFO		1	.786**	.816*
RPC			1	.478**
RDE				1

5.4 Multivariate Analysis

Ordinary least squares procedures (OLS) are used to estimate the models stated in Section 4.4.3. The results of the above models are reported in the following subsections.

5.4.1 Abnormal cash flows from operation (RCFO) and GOVOWN and control variables

Table 5.3 reports the results of the regression of GOVOWN on the RCFO and control variables. The results show that GOVOWN has significant negative association with dependant variable (RCFO). The results indicate that government ownership had an impact on the real earnings management practices involving cash flow from operations.

The significant negative association found between RCFO with SIZE, BIG4 and BODIND. The significant negative relationship between RCFO and SIZE is in line with the findings of previous studies that argue information asymmetry is often smaller for large firms because they produce more public information. This in turn limit aggressive financial practices. Besides, according to Wahab (2007) higher-quality auditors are more likely to ensure greater transparency and to eliminate mistakes in financial statements since they are more likely to protect their reputation. Thus, clients of higher-quality auditors are more likely to have conservative financial reporting practices as they have better corporate governance. With regards to board independence, the results consistent prior studies found evidence that supports the effective monitoring role played by independent directors in deterring accounting fraud (Beasley, 1996) and earnings management via discretionary accrual (Xie et al., 2003; Klein, 2002; Peasnell et al., 2000; Su, 2001).

In addition, there are positive associations found between RCFO with LEVERAGE and MUSCEO, consistent with the findings of Sweeney (1992) documented that managers of firms approaching debt covenant default are more likely to make income-increasing changes in periods before the violation. She also found that managers continue to make income-increasing changes in years following the first year of default.

Table 5.3: Results of the Relation between Abnormal cash flows from operation (RCFO) and GOVOWN and control variables

$$RCFO_{ft} = \alpha + \alpha_1 GOVOWN_{ft} + + f(control\ variables) + \xi \qquad (1)$$

Variables	Predicted Sign	Coefficient	t-stat	P value
GOVOWN	-	-.007	-.523	.000
Control Variables: Firm's specific characteristics

R-Square		45.4		
Adjusted R-Square		39.9		

5.4.2 Abnormal production costs (RPC) and GOVOWN and control variables

The results of estimating the effects GOVOWN on RPC and control variables are presented in Table 5.4. GOVOWN has significant negative association with dependant variable (RPC). The significant association infers that the government ownership deter real earnings management practices involving production costs in Malaysian listed firms.

For the control variables, RPC has significant negative association with SIZE. In line with the findings of previous studies (Gu et. al., 2005 and Saleh et al., 2005). The large firms enjoy more of the benefits of economy of scale and economy of scope, thus making them satisfied with their position and restraining them from exercising earnings management.

Of the firms' board characteristics variables, BODIND and MUSCh have a significant negative association with RPC. These results suggest that firms that have Muslim chairman and more independent non-executive directors on the board and are less likely to practice earnings management.

In addition, there are significant positive association between RPC with GROWTH, PROFIT and LEVERAGE.

Table 5.4: Results of the Relation between Abnormal production costs (RPC) and GOVOWN and control variables

$$RPC_{ft} = \alpha + \alpha_1 GOVOWN_{ft} + f(control\ variables) + \xi \qquad (2)$$

Variables	Predicted Sign	Coefficient	t-stat	P value

Adjusted R-Square		36.3		

5.4.3 Abnormal discretionary expenses (RDE) and GOVOWN and control variables

GOVOWN has a significant negative association with abnormal discretionary expenses which in turn supports the current study that government ownership is able to mitigate effectively the real earnings management practices involving discretionary expenses.

For the control variables, RDE has only significant negative association with SIZE, BIG4 and BODSIZE. The results suggest that larger firms with a higher composition of directors on the board and hired Big 4 Auditors are less likely to practice real earnings management via discretionary expenses.

Table 5.5: Results of the Relation between Abnormal discretionary expenses (RDE) and GOVOWN and control variables

$$RDE_{ft} = \alpha + \alpha_1 GOVOWN_{ft} + f(\text{control variables}) + \xi \quad (3)$$

6.0 Summary and Conclusion

The purpose of this paper is to examine the association between government ownership and real earnings management. To capture real earnings management, the study uses three different measures: the abnormal cash flows, the abnormal production costs, and the abnormal discretionary expenses developed by Rochowdhury (2006). The study employs a sample of 329 Malaysian GLCs firm-year observation from 2001 to 2014.

Overall, the results of the study support the view that government ownership limit real earnings management. In particular, the findings indicate that there is a significant negative relation between government ownership and all measure of real earnings management: RCFO, RPC and RDE. The results show that Malaysian GLCs are less likely to manage accounting number by using abnormal discretionary cash flow from operation, abnormal discretionary production cost and abnormal discretionary expenses.

In general, the findings are consistent with the findings of Hoang et al. (2014), Wang and Yung (2011) and Jow et al. (2007), who find that government owned firms are less likely involved in earnings management. These results support previous argument on alignment hypothesis that government ownership is a monitoring mechanism in limiting managerial opportunism in business organizations which in turn increase the quality of accounting numbers.

Abstract

Knowledge plays an important role in firms' internationalization process. Building on well established theories, our research studies explores the effects of Realized Absorptive Capacity (knowledge transformation and knowledge exploitation) on export performance of Portuguese small and medium enterprises (SMEs) of Portuguese footwear industry.Based on survey data from 42 firms, our empirical results indicate that knowledge exploitation and knowledge transformation have a positive and significant influence on export performance.Finally, the main limitation of this study is related to the sample size, since it was difficult to find companies willing to collaborate with this kind of research.

Keywords: absorptive capacity, knowledge transformation, knowledge exploitation, export performance, SMEs, Portuguese footwear industry.

Introduction

In a dynamic and turbulent environment, knowledge represents a critical resource to create value and to develop and sustain competitive advantages (Teece, Pisano, & Shuen, 1997). However, fast changing environments, technologies and competitiveness intensify the challenges firms face in attaining self-sufficiency in knowledge creation (Camisón & Forés, 2010).

Several strategic management scholars argue that Resource-Based View (RBV) has basically "inward" orientation. Although RBV recognizes that "the value of the firm's resources and capabilities is determined by the market context within which the firm is operating" (Barney, 2001, p. 645), it does not address the processes of converting resources and capabilities into customer value (Möller, 2006).

A second body of literature in the field of strategic management has focused on dynamic capabilities (for a review see Barreto, 2010). The firms' success depends not only on its' resources and capabilities, but also the ability to adapt itself to the industry contingencies and the markets in which operates. Firms may possess resources but must display dynamic capabilities otherwise shareholder value will be destroyed (Bowman & Ambrosini, 2003). It is in this context that emerges the Dynamic Capabilities View (DCV) (Amit & Schoemaker, 1993; Teece et al., 1997) to support the adjustment to environmental change.

DCV is not divergent but rather an important stream of RBV to gain competitive advantage in increasingly demanding environments (Ambrosini & Bowman, 2009; Barreto, 2010; Eisenhardt & Martin, 2000; Wang & Ahmed, 2007). Monteiro, Soares & Rua (in press) defend that in versatile markets the firms' capabilities should be dynamic and managers must display the ability to ensure consistency between the business environment and strategy in order to continuously renew skills.

Absorptive capacity (ACAP) has become one of the most significant constructs in the last twenty years. Absorptive capacity is the dynamic capability that allows firms to gain and sustain a competitive advantage through the management of the external knowledge (Camisón & Forés, 2010).

Cohen and Levinthal (1990) conceptualize ACAP as the firms' ability to identify, assimilate, and exploit knowledge aquired from external sources. As such, ACAP facilitates knowledge accumulation and its subsequent use. Zahra and George (2002) broaden the concept of ACAP from the original three dimensions (identify, assimilate, and exploit) to four dimensions (acquire, assimilate, transform, and exploit).

Studies within the strategic management literature have highlighted the important role of ACAP in achieving higher firm performance. Indeed, absorptive capacity is a mean of attaining superior financial performance, and transforming external knowledge inflows into performance gains (Kostopoulos, Papalexandris, Papachroni, & Ioannou, 2011).

As the importance of internationalization grows for many firms around the globe, there is an increasing interest in the strategic determinants that predict export performance. Therefore, research on export performance has developed exponentially. This increase interest of the academia was originated from the various macro and micro-level benefits associated with export development. At the macro-level, superior export performance is a cost-effective vehicle for economic growth, employment creation and a general improvement in the standards of living. There are countless benefits at the firm-level including opportunities for growth, larger market shares, better margins and diversification of risk (Kahiya & Dean, 2014).

Building on well established theories, our research aims at exploring the influence of absorptive capacity in export performance of Portuguese SMEs exporting footwear, by analyzing the contributions of this capability in such performance.

The findings of this study will have important implications for both academics and practitioners. By building on the literature of absorptive capacity and export performance, this study aims to support the strategic development of business management policies designed to increase firms' performance in foreign markets and add value to the current context of change. In addition, the results will provide guidance to business practitioners; because they will indicate which absorptive capacities are the best predictors for export success. The study also adds to the absorptive capacity literature by empirically validating it as a latent construct that captures the dimensions of acquiring, assimilating, transforming and exploiting knowledge.

In the next section, we present the theoretical background of the research and develop our hypotheses. We then describe our methodology and present our results. Finally, we discuss our results and conclude with managerial implications, limitations and future research opportunities.

1. Theoretical Framework

1.1. Dynamic Capabilities View

Dynamic capabilities as a mind-set constantly integrate, reconfigure, renew and recreate its core capabilities in response to the ever changing environment in order to achieve and sustain competitive advantage (Wang & Ahmed, 2007). Moreover, these capabilities sense and shape opportunities and threats, seize opportunities, and maintain competitiveness by enhancing, combining, protecting, and reconfiguring the businesses' intangible and tangible resources (Teece, 2007).

Barreto (2010, p. 271) argued that a "dynamic capability is the firm's potential to systematically solve problems, formed by its propensity to sense opportunities and threats, to make timely and market-oriented decisions, and to change its resource base".

It is important to distinguish between dynamic capabilities and RBV's capabilities since they are considered to be distinct constructs (Ambrosini & Bowman, 2009). On one hand, an operational capability is a high level routine (or collection of routines) which, together with the inputs, provides the management a set of decision options for the production of outputs (Winter, 2000). We highlight the term routine, which is understood as a learned behaviour, extremely structured, repetitive and based on technical knowledge. Thus, these operational capabilities allows the company to sustain itself in the present (Winter, 2003), usually involving the execution and the coordination of a variety of tasks to perform an activity, such as production of a particular product (Helfat & Peteraf, 2003).

On the other hand, dynamic capabilities enable companies to create, develop and protect resources allowing them to attain superior performance in the long run, are constructed (not acquired in the market), dependent on experience and are embedded in the company's organizational processes (Ambrosini & Bowman, 2009), not directly affecting the outputs, but contributing through the impact they have on operational capabilities (Teece et al., 1997). These capabilities refer to a firm's capacity to deploy resources, usually in combination, using both explicit and tacit elements (such as know-how and leadership). For this reason, capabilities are often firm-specific and are developed over time through complex interactions between the firm's resources (Amit & Schoemaker, 1993).

After a literature review, Wang & Ahmed (2007) identify three main component factors of dynamic capabilities, namely adaptive capability (ambidexterity), absorptive capability and innovative capability. Adaptive capability is the firm's ability to timely adapt itself by aligning resources and capabilities with environmental changes. Absorptive capability takes external knowledge combines it with internal knowledge and absorb it for internal usage. Innovative capability turns firm's innovativeness in marketplace-based advantage. In this paper the focus is on the absorptive capability.

1.2. Absorptive Capability

In order to survive certain pressures, companies need to recognize, assimilate and apply new external knowledge for commercial purposes (Jansen, Van Den Bosch, & Volberda, 2005). This ability, known as absorptive capacity (ACAP) (Cohen & Levinthal, 1990), emerges as an underlying theme in the organizational strategy research (Jansen et al., 2005).

ACAP is a good example of a dynamic capability since it is embedded in a firm's routines. It combines the firm's resources and capabilities in such a way that together they influence "the firm's ability to create and deploy the knowledge necessary to build other organizational capabilities" (Zahra & George, 2002; p. 188).

Firms, therefore, need to continually analyze and interpret changing market trends and quickly recognize new opportunities in order to create competitive products (Tzokas, Kim, Akbar & Al-Dajani, 2015).

Cohen & Levinthal (1990) presented a definition of ACAP most widely quoted by academic research, as the companie's ability to identify, assimilate and exploit new knowledge. Thus, this ability access and use new external knowledge, regarded as an intangible asset, is critical to success and depends mainly on prior knowledge level, since it is this knowledge that will facilitate the identification and processing of new one. This prior knowledge not only includes the basic capabilities, such as shared language, but also recent technological and scientific data or learning skills. By analyzing this definition is found that absorptive capacity of knowledge only three dimensions: the ability to acquire external knowledge; the ability to assimilate it inside; and the ability to apply it.

The ACAP construct encompasses an outward-looking perspective that deals with the identification and generation of useful external knowledge and information and an inward-looking component that is related with how this knowledge is analyzed, combined with existing knowledge, and implemented in new products, new technological approaches, or new organizational capabilities (Cohen & Levinthal, 1990).

According to Zahra & George (2002) ACAP is divided in Potential Absorptive Capacity (PACAP), including knowledge acquisition and assimilation, and Realized Absorptive Capacity (RACAP) that focuses on transformation and exploitation of that knowledge. PACAP reflects the companies' ability to acquire and assimilate knowledge that is vital for their activities. Knowledge acquisition the identification and acquisition and assimilation is related to routines and processes that permit to analyze, process, interpret and understand the external information. RACAP includes knowledge transformation and exploitation, where transformation is the ability to develop and perfect routines that facilitate the integration of newly acquired knowledge in existing one, exploitation are routines which enhance existing skills or create new ones by incorporating acquired and transformed knowledge internally.

Jansen et al. (2005) defend that, although company's exposure to new knowledge, is not sufficient condition to successfully incorporate it, as it needs to develop organizational mechanisms which enable to synthesize and apply newly acquired knowledge in order to cope and enhance each ACAP dimension. Thus, there are coordination mechanisms that increase the exchange of knowledge between sectors and hierarchies, like multitasking teams, participation in decision-making and job rotation. These mechanisms bring together different sources of expertise and increase lateral interaction between functional areas. The system mechanisms are behaviour programs that reduce established deviations, such as routines and formalization. Socialization mechanisms create a broad and tacit understanding of appropriate rules of action, contributing to a common code of communication.

Studying absorptive capacity offers fascinating insights for the strategic management literature and provide new information regarding how firms may develop important sources of sustainable competitive advantages (Jansen et al., 2005), reason why the focus of our study lies on the RACAP.

1.3. Export Performance

The development of exports is of great importance, both at macro and micro levels, contributing to economic and social development of nations, helping the industry to improve and increase productivity and create jobs. At company level, through market diversification, exports provide an opportunity for them to become less dependent on the domestic market, gaining new customers, exploiting economies of scale and achieving lower production costs while producing more efficiently (Okpara, 2009).

In this sense, exports is a more attractive way to enter international markets, especially for SMEs, in comparison with other alternatives, either joint ventures or setting up subsidiaries, which involve spending a large number of resources (e.g. Dhanaraj & Beamish, 2003; Piercy, Kaleka & Katsikeas, 1998), does not create high risk and commitment and allows greater flexibility in adjusting the volume of goods to different export markets (Lu & Beamish, 2002).

On one hand, a company's export activity starts to fulfil certain goals, which may be economic (such as increasing profits and sales) and / or strategic (such as diversification of markets, gaining market share and increasing brand reputation) (Cavusgil & Zou, 1994).

On the other hand, the export motivation may result from proactive or reactive actions. The proactive actions are advantage of profit, introduction of a single product, technological advantage, and exclusive information, commitment of management, tax benefits and economies of scale. The reactive motivations are identifying competitive pressures, excess production capacity, sales decrease in domestic market, saturation of domestic market and proximity of customers and landing ports (Wood & Robertson, 1997).

1.4. Hypotheses Derivation

Dynamic capabilities refer to "the firm's ability to integrate, build, and reconfigure internal and external competences to address rapidly changing environments" (Teece et al., 1997, p. 516). By "environment" the RBV literature usually refers to the competitive business environment. Markets

had become hypercompetitive, making it increasingly difficult to maintain competitive advantage over time (Barreto, 2010).

Dynamic capabilities enable companies to create, develop and protect resources to achieve superior performance in the long run, are built (not acquired), experience dependent and are embedded in organizational processes (Ambrosini & Bowman, 2009), not directly affecting outputs, but contributing through the impact they have on operational capabilities (Teece et al., 1997). Maintaining these capabilities requires a management that is able to recognize adversity and trends configure and reconfigure resources, adapt processes and organizational structures in order to create and seize opportunities, while remaining aligned with customer preferences. Indeed, dynamic capabilities allow businesses to achieve superior long-term performance (Teece, 2007). Ultimately, the following hypotheses are tested:

H2: *Knowledge transformation has a positive effect on export performance.*

H1: *Knowledge exploitation has a positive effect on export performance*.

2. Methods

2.1. Setting and Data Collection

To test the hypothesis a sample of Portuguese footwear companies was used, that meet the following criteria: companies in which at least 50% of income comes from exports of goods, or companies in which at least 10% of income comes from exports of goods and the export value is higher than 150.000 Euros (INE, 2011).

Data collection was implemented through electronic questionnaire, associating a link to the survey that was online. To reduce misunderstandings, the questionnaire was validated by the research department of APICCAPS.

For information regarding companies the *Associação Portuguesa dos Industriais de Calçado, Componentes, Artigos em Pele e seus Sucedâneos* (APICCAPS) was contacted. We were provided with a database of 231 companies (company name, telephone contact, email, CAE, export markets, export intensity and capital origin). Only 167 companies fulfilled the parameters, and were contacted by email by APICCAPS to respond to the questionnaire. Subsequently, all companies were contacted by the authors via e-mail and telephone, to ensure a higher rate of valid responses. The questionnaires began on April 22, 2014 and ended on July 22, 2014. After finishing the data collection period, 42 valid questionnaires were received, representing a 25% response rate (Table 1). This response rate is considered quite satisfactory, given that the average of top management survey response rates are in the range of 15%-20% (Menon, Bharadwaj, Adidam & Edison, 1999).

Table 1 : Data Summary

Universe of analysis - Portuguese SMEs of footwear
Sample - a non-probabilistic and convenient
Population – 367 firms
Sample – 167 firms
Response rate – 25%
Valid responses - 42
Time period – April 22 to July 22 of 2014

In this investigation we chose a non-probabilistic and convenient sample since it respondent were chosen for being members of APICCAPS.

2.2. Measures

To measure RACAP constructs, understanding knowledge transformation and knowledge exploitation, and based in Jansen et al. (2005), it was operationalized the company's ability to transform it through six questions and the ability to explore new external knowledge into their current operations through six questions (e.g. Jansen et al., 2005; Zahra & George, 2002). A five point Likert scale was used to measure each item, where 1 means "strongly disagree" and 5 "strongly agree".

Okpara's scale (2009) was used to assess export performance, comprising profitability indicators of sales growth, profit, activities, operations and performance in general. A five point Likert scale was used to measure each item, where 1 means "strongly disagree" and 5 "strongly agree". It is important to note that companies evaluated absorptive capacity and export performance relative to their major competitors in the export market(s).

3. Results and Analysis

3.1 Reliability Analysis

In order to verify the reliability of overall variables we estimated the stability and internal consistency through Cronbach's alpha (α). Generally, an instrument or test is classified with appropriate reliability when α is higher or equal to 0.70 (Nunnally, 1978). However, in some research scenarios in social sciences an α of 0.60 is considered acceptable, as long as the results are interpreted with caution and the context is taken into account (DeVellis, 2012). For the present study we used the scale proposed by Pestana & Gageiro (2008).

The result of 0.938 achieved for all of variables is considered excellent, confirming the sample's internal consistency. It was also conducted an internal consistency test for all variables in each construct to assess their reliability (Table 2).

Table 2: Internal consistency test by construct (Cronbach's Alpha)

Construct	*Cronbach's α*	Items Nr.	N	Analysis
Knowledge transformation	.873	6	42	very good
Knowledge exploitation	.897	6	42	very good
Export performance	.927	5	42	excellent

We found that knowledge exploitation and knowledge transformation have a very good consistency and that export performance have excellent consistency.

3.2. Exploratory Factor Analysis

Factor analysis is a technique whose primary purpose is to organize the structure of a large number of variables by defining sets of variables that are highly interrelated, known as factors. These groups of factors are assumed to represent dimensions within the data. The general purpose of factor analytic techniques is to find a way to summarize the information contained in a number of original variables into a smaller set of new dimensions with a minimum loss of information (Hair, Black, Babin, & Anderson, 2014; Pestana & Gageiro, 2008). After factor extraction, we submit each factor to varimax rotation to achieve a simplified factor structure (Marôco, 2011).

Knowledge transformation

The factor analysis, with Varimax rotation, of *Knowledge Transformation* presents a scale with 6 items, distributed by one factor that explained 62.0% of total variance, whose saturations range between 0.893 and 0.662. The internal consistency of the factor is α=0.873, indicating a very good

internal consistency. KMO test confirm a medium correlation between the variables (0.796). Bartlett's sphericity test registered a value of $\chi^2(15, N=42)=130.981$, $p<0.05$, therefore is confirmed that $\chi^2>\chi_{0.95}^2$, so the null hypothesis is rejected and the variables are correlated.

Knowledge exploitation

Concerning *Knowledge Exploitation*, in the factor analysis, with Varimax rotation, we got a scale with 6 items, distributed by one factor that explained 66.6% of total variance, whose saturations range between 0,906 and 0.730. The internal consistency of the factor is $\alpha=0.807$. These values indicate that these dimensions presented a reasonable and excellent internal consistency. KMO test confirm a medium correlation between the variables (0.866). Bartlett's sphericity test registered a value of $\chi^2(15, N=42)=140.879$, $p<0.05$, therefore is confirmed that $\chi^2>\chi_{0.95}^2$, so the null hypothesis is rejected and the variables are correlated.

Export performance

In the factor analysis, with Varimax rotation, of these construct we got a scale with one factor and there was no need to delete items. A scale with 5 items was obtained, which explained 77.9% of total variance, whose saturations range between 0.918 and 0.850. The internal consistency is excellent ($\alpha=0.927$). KMO test point to a good correlation between the variables (0.814). Bartlett's sphericity test registered a value of $\chi^2(10, N=42)=171.982$, $p<0.05$, therefore is confirmed that $\chi^2>\chi_{0.95}^2$, so the null hypothesis is rejected and the variables are correlated.

3.3. Multiple Regression Analysis

Multiple regression analysis is a statistical technique that is used to analyze the relationship between a single dependent (criterion) variable and several independent (predictor) variables. The objective of multiple regression analysis is to use the independent variables whose values are known to predict the single dependent value selected by the researcher. Each independent variable is weighted by the regression analysis procedure to ensure maximal prediction from the set of independent variables.

The most commonly used measure of predictive accuracy for the regression model is the coefficient of determination (R^2). This coefficient measures the proportion of total variability that can be explained by regression ($0\leq R\leq 1$), measuring the effect of independent variables on the dependent variable. When $R^2=0$ the model clearly does not adjust to data and when $R^2=1$ the adjustment is perfect. In social sciences when $R^2>0.500$ the adjustment is considered acceptable (Marôco, 2011). In the table 3 we present the results of the multiple regression analysis of our model. Univariate analysis of variance (ANOVA) is used to determine, on the basis of one dependent measure, whether samples are from populations with equal means(hair) and allows to test the hypotheses: H0: $\rho^2=0$ *vs.* H1: $\rho^2\neq 0$.

Table 3 : Summary and ANOVA regression[c]

Model	R	R^2	Adj. R^2	Standard error	F	Sig.
1[a]	.313	.098	.075	.96156221	4.343	.044
2[b]	.442	.196	.176	.90801912	9.727	.003

a. Predictors: (Constant) Knowledge transformation.
b. Predictors: (Constant) Knowledge exploitation.
c. Dependent variable: Export performance.

The previous table present for model 1 a ρ-*value*=0.044 ($p<0.05$) and for model 2 a ρ-*value*=0.003 ($p<0.05$), so H0 is rejected in favour of H1 and H2, supporting the hypotheses of our study.

4. Discussion and Conclusion

The Portuguese footwear industry faces considerable challenges, not only concerning the international markets crisis, but also regarding consumption patterns. The reduction of shoe design

lifecycles has consequences on the offer. On one hand, the products have to be adapted to different segments specific needs and tastes (custom design, new models in small series, etc.), on the other hand, manufacture processes must be increasingly flexible, adopt just-in-time production, invest in the brand, qualified personnel, technology and innovation (APICCAPS, 2013).

The main purpose of this study is to analyze the effects of RACAP (knowledge transformation and knowledge exploitation) on export performance of SMEs. We conducted an empirical research based on a sample of 42 companies, which were applied a questionnaire in order to exploit data to test hypotheses, using proceedings and statistical techniques. It is important to note that companies evaluated absorptive capacity and export performance relative to their major competitors in the export market(s), so the results should be interpreted based on these two aspects.

This study also demonstrated that the company's absorptive capacity of knowledge transformation and knowledge exploitation have a positive and significant effect on their performance. The analyzed companies are able to transform and exploit knowledge through informal knowledge gather, clear definition of tasks, analysis and discussion of market trends and new product development, among others.

Dynamic capabilities can take a variety of forms and be involved in different functions, but the most important common characteristics are that they are higher level capabilities which provide opportunities for knowledge gathering and sharing, constant updating the operational processes, interaction with the environment, and decision-making evaluations (Easterby-Smith, Lyles, & Peteraf, 2009). However, the existence of common features does not imply that any particular dynamic capability is exactly alike across firms, rather they could be developed from different starting points and take unique paths (Eisenhardt & Martin, 2000).

In fact, according to the industrial organization, a company should find a favourable position in its industry from which it can better defend against competitive forces, or to influence them in his favour through strategic actions such as raising barriers to entry, etc. (Porter, 1980). This perspective is consistent with Eisenhardt and Martin (2000) regarding the uniqueness of paths. The results of this study confirm that dynamic capabilities enable firms to achieve superior long-term performance (Teece, 2007).

4.1. Theoretical and Practical Implications

The findings of this research will have important implications for both academics and practitioners. The study adds to the absorptive capacity literature by empirically validating it as a latent construct that captures the dimensions of transforming and exploiting knowledge.

It is known that strategy includes deliberate and emergent initiatives adopted by management, comprising resource and capabilities use to improve business performance (Nag, Hambrick & Chen, 2007). The findings are a contribution to clarify the influence of absorptive capacity on the company's exports performance. This study also enabled a thorough analysis of a highly important industry for national exports, such as footwear industry, allowing understanding that absorptive capacity, as an industry strategic determinant, enhancing exports performance.

To stay competitive, companies must make an internal assessment in order to find what resources and capabilities give them advantage over competitors. Thus, the challenge of strategy consists in selecting or creating an environmental context where capabilities and resources can provide competitive advantages (Porter & Montgomery, 1998).

Jansen et al. (2005) defend that companies need to develop organizational mechanisms to combine and apply newly acquired knowledge in order to deal and enhance each absorptive capacity dimension. In this study is notorious the importance of knowledge absorptive capacity to business performance. It is essential that business owners are able to interpret, integrate and apply external knowledge in order to systematically analyze change in the target market and to incorporate this knowledge in their processes to enhance performance.

In addition, the results provide guidance to business practitioners; because they indicate which absorptive capacities are the best predictors for export success. Companies are a bundle of resources and capabilities (Peteraf, 1993), it is essential to understand and identify which resources are relevant to gain competitive advantage and superior performance. In this study it is obvious the importance of absorptive capacity to the firms' performance. Business owners must be able to interpret, integrate and apply external knowledge in order to systematically analyze the changes that arise in their target market(s) and to incorporate this knowledge into their processes, to identify the present and future needs and market trends, anticipate changes in demand and seek new business opportunities.

By building on the literature of absorptive capacity and export performance, this study aims to support the strategic development of business management policies designed to increase firms' performance in foreign markets and add value to the current context of change.

4.2. Research Limitations

The main limitation of this study is related to the sample size, since it was difficult to find companies with the willingness to collaborate in this type of research. The sample is non-probabilistic and convenience and cannot be used to infer to the general population. The study findings should therefore be analyzed with caution.

Most responses were based on subjective judgment of respondents. Although the literature identifies the advantages of subjective measures to evaluate the exports performance, it is recognized that some answers may not represent the reality of business performance in foreign markets.

The fact that the research does not consider the effect of control variables such as size, age, location and target market of the respondents can be seen as a limitation.

Finally, the fact that this study considered only export as internationalization can also be appointed as a limitation.

4.3. Future Lines of Research

In future work, we suggest that the model is used in a sample with a higher number of observations to confirm these results.

We further suggest pursuing with the investigation of strategic management in Portugal, focusing in other sectors of national economy, so that in the future one can make a comparison with similar studies, allowing realizing and finding new factors that enhance exports performance.

Finally, the moderating effect of strategic variables (e.g. competitive advantage) in the relationship between absorptive capacity and export performance should be studied.

Abstract

Risk reporting is important for business survival as it is being used to disseminate information pertaining to risk and its impacts to potential investors and shareholders. In a challenging economic environment, it is undeniable that the mandatory risk information is a central focus as compared to voluntary risk information. However, business practitioners have raised their concern on insufficient information on risky business events being reported publicly as it is evidenced to have impacts toward business valuation and its survival. Thus, this study is carried out to examine the relation between survivability decisions of the business that influence their risk reporting practices. The sample was drawn from 652 non-financial companies listed on the main Board of Bursa Malaysia for the financial year end 2006 to 2009. The research approach applied the content analysis of listed companies' published annual reports. The findings revealed that there were significant influences of survivability decisions as proxied by revenue growth, industry concentration and leverage; on the voluntary risk disclosure.

Keywords: Business survival, risk reporting, revenue growth

Introduction

The susceptibility of economic challenges around the world occur due to several circumstances such as advances in technology, declining in commodity prices and the strengthening of US currency. This phenomenon had really influenced the national economic climate. Indeed, apart from that, the Malaysian economy landscape was severely affected by the instability of domestic politics and 'unappealing' government policies which appear that majority of the people are struggling with the rising cost of living that influences consumers spending behaviours. Not to mention, all these challenges are expected to put businesses in deep trouble in the long run, thus, the risk is now becoming a continuous focus. This raises concern about whether risk has been managed and communicated effectively among business practitioners. With regards to those issues, the only reliable medium could be used by the shareholders and potential investors to retrieve information pertaining risk and its impacts are from the companies' annual reports. The information is paramount as it indicates how management disseminates such information for business survival.

Sufficient reports focusing on risk and its impacts has been reported as increasing in demand, in line with the hope that the management of risk being practically improved as well. The specific narrative disclosure on risk management has not imposed as a mandatory statement for many countries. Therefore, the way the risk information being reported is likely depending on the management discretion. The management might indicate their judgements based on what the impacts of risky events that they may foresee toward business survival. Apparently, studies have shown that companies often disclose vague and limited amount of risk information; as they have a basis not to disclose more since such disclosure was

considered as the voluntary effort of the individual company. On the other hand, lacking sufficient risk information publicly may result in false impressions of actual threats or impacts on business activities (e.g. product development, marketing, technological innovations, and daily administrative activities). Unfortunately, a business might lose their competitive advantage as it will affect investment evaluation when it is based on inaccurate information and unclear explanation about the impact of potential risks. In a severe situation, the capability of the management on overall business operations would be affected due to misinterpretation of the company's current decisions.

A number of researchers had conducted studies on the narrative report, both on the mandatory and voluntary risk reporting practices. Some prior researches have indicated that managers have the tendency to voluntarily disclose risk information when there are valid reasons to signal something important to market participants (Cannizzaro & Weiner, 2015; Guidry & Patten, 2010; Mukherjee, Sen, & Pattanayak, 2010). For instance, possible signalling underlying reasons would be to observe market reaction towards disclosure strategy, to avoid uncertainty resulting the conflict of investors-management and whether the strategy for meeting financial obligations is met as expected. Those reasoning would be a basis for this study to investigate other factors from another angle based on the debates emerged on the role of strategic decisions in providing a signal on business survival in a long-run. Thus, this study is carried out to examine the relationship between signalling mechanisms from the business strategy point of view and the decision to voluntarily disclose risk information.

The remaining of this paper encompasses the literature review and hypotheses generation, methodology, data analysis and discussion, and conclusion.

Literature Review and Hypotheses Generation

Signalling Theory and Voluntary Risk Disclosure

Prior empirical literatures observed the association of applied information signal to potential investors and the good governance process (Subramaniam, McManus, & Zhang, 2009), quality of reporting (Elzahar & Hussainey, 2012), corporate management (Ndofor & Levitas, 2004), and the corporate financial structure and strategic decisions (Hussainey & Aal-Eisa, 2009). These studies considered that the availability of an informative signal for business survival would help to reduce the information asymmetry between the manager and investors.

The signalling theory contends that when the firms believe they are above average performance as compared to other firms, they would prefer to signal their outstanding achievements to attract potential investment in order to create high firm value (Campbell et al., 2001). This in turn, would avoid misinterpretation of company performance or adverse selection of product quality through the absence of information held by the external users. Large-sized firms tend to send a signal to indicate that they have achieved acceptable satisfactory performance since these firms are usually considered to be highly profitable firms and possess high value of assets. Therefore, when firms choose to use the voluntary disclosure mechanism to reduce the information asymmetry, it indicates a good sign that the firms are willing to portray themselves as being at a better level than others, probably either in managing the governance of the firms or attaining exceptional performance (Barako, Hancock, & Izan, 2006). As a result, when the information is shared through the public medium, the investors exert increased monitoring ability that may alter their risk perception concerning the companies' prospective business (Khlifi & Bouri, 2010).

Companies may signal a good information to obtain some economic benefit, thus, managers tend to reveal the superior information as not disclosing such information may indicate a sign of hidden substantial information that leads to another issue of adverse selection. The adverse selection is a form of

an agency problem that might exist because the manager possesses more information than the shareholders do (Darrough & Stoughton, 1986). Thus, disclosure may be used regularly as it indicates a direct signal of the quality of the company that can be used to reduce the possibility of adverse selection (Patelli & Prencipe, 2007). However, even with the voluntary disclosure of information, Pae (2002) contends that the information receiver or investor still does not know whether the firm is providing actual facts or not, and at what level firms are willing to disclose such information, especially when it involves substantial and competitive information in an effort to get as much information to aid in their investment decisions.

Kirmani and Rao (2000) explore the different approaches of high quality firms and low quality firms, in as much as the former firms will signal the true indication to distinguish themselves from the latter firms. This is because each firm possesses both positive and negative information, which they need to decide whether or not to convey to the investors. Most of the time, the companies will probably communicate positive information rather than negative to reduce the information asymmetry (Connelly, Certo, Ireland, & Reutzel, 2011). In a particular situation when firms face intense business competition, they intend to communicate about severe uncertainty and risks that might arise from the changes in industry policy, economic structure or market regulations. However, companies' financial performance are able to reduce information asymmetry as it links to reduce cost of capital and increase firm valuation, thus these information are relevant to potential investors (Elzahar, Hussainey, Mazzi, & Tsalavoutas, 2015).

Capital Intensity

Capital intensity may reflect the barrier to entry a competitive market and could capture firms' financing initiatives related to capital market benefits and proprietary costs. In particular less competitive industry, a higher entry barrier is observed as the nature of information would be less complex due to improving ability in earnings prediction (Haw, Hu, & Lee, 2015). Clarkson, Fang, Li and Richardson (2010) established a notion that a high entry barrier is much influenced by high capital intensity, thus lowering the potential threat to entrants. In other words, firms with high proprietary costs in relation to capital intensity are expected to provide greater disclosure of voluntary information compared to firms with low capital intensity. This could be inferred as protecting potential competitors from entering a highly concentrated industry by revealing a firm's competitive advantage through public announcements. Verrecchia (1983) concludes that the level of voluntary disclosure (e.g. high or low) might also influence a firm's presence in a highly competitive market, as such disclosure might contain proprietary information. Thus, it is predicted that firms with high capital intensity would be likely to voluntarily disclose more risk information than firms with low capital intensity to avoid potential entrants to the existing market as well as to sustain its presence in the market. From the above reasoning, the following hypothesis is developed from the perspective of capital intensity:

H1: There is a significant positive relationship between capital intensity and risk reporting practices.

Profitability

Profitability may be regarded as proprietary information to the firms as this particular information could lead to the lessening of a manager's disclosure incentive. To attract investors' attention, companies are likely to disclose favourable information rather than unfavourable information as it could increase share prices (Das, Dixon, & Michael, 2015; Verrecchia, 1983). Related literature notes significant initiatives that can signal superior performance, increase investors' confidence and reduce information asymmetry (Odera, Scott, & Gow, 2016). Although prior studies have found a positive significant relationship between profitability and disclosure level, Odera et al. (2016) find an inverse significant relationship between profitability and voluntary disclosure levels. This is consistent with Leuz (2003) who anticipates that proprietary costs influence a manager's voluntary disclosure decision. She presumes that firms that perform well are unlikely to disclose more information to minimise potential detriment when the

information is being used by competitors, thus lessening the opportunity of potential entrants to enter the market (Depoers, 2000). Therefore, high profitability firms, which represent stable firms, are expected to increase information disclosure for the public as it would be a signal to the potential competitors as well as others that they are willing to share substantial risk information to gain more trust and confidence from the investors. Based on the arguments, the following hypothesis is formulated based on firm profitability:

H2: There is a significant negative relationship between firm profitability and risk reporting practices.

Revenue Growth

Information on growth is always a cause for concern for large firms that operate in a highly competitive industry (Brauninger & Vopel, 2010). In relation to the sign of financial performance indicating the growth opportunity of firms, the revenue growth and industry concentration measures are used as a valid proxy based on prior empirical studies (Darus, Arshad, Taylor, & Othman, 2008; Das et al., 2015; Elzahar et al., 2015). Moreover, Darus et al. (2008) and Hassanein and Hussainey (2015) show that the proxy of potential competition measured by investment growth opportunities has the potential to affect managers' voluntary disclosure decisions. Information concerning the intensity of industrial competition between active firms in the industry tends to influence the level of competitive information being disclosed by the well-performing firms (Hassanein & Hussainey, 2015). For instance, Elzahar et al. (2015) found the usefulness of revenue generated figures in determining companies' performance that would indicate differences in disclosure level. Gelb and Greenstein (2004) contend that most firms treat financial performance as a factor that restrains them from disclosing more information rather than the influence are exerted through government regulations. Also, the existence of competition has been evidenced to induce lower information, since intense competition would induce a greater response from competitors through the offering of a better quality product or service (Li, 2010). Thus, this study expects prospective firms to create a more competitive environment; however, the competitive environment has a tendency to discourage voluntary risk disclosure in order to avoid competitors' exploitation, which, in turn, would have a severe risk impact on the firm. Therefore, due to the above reasoning, the following hypothesis is formulated:

H3: There is a significant negative relationship between firm revenue growth and risk reporting practices.

Industry Concentration

The industry concentration measure has been viewed as another approach to assessing the increase in firm growth. Furthermore, Alvarez et al. (2008) clearly define that a concentrated industry applies when the industry is being represented by a limited number of firms that have the same proportion of shares of sales. Since a small number of firms hold the same market share, the industry can be considered a competitive industry. Firms may exhibit themselves as more competitive than their competitors by disclosing greater voluntary information when they have a large portion of market concentration (Villalonga & Amit, 2010). In similar vein, Demsetz and Villalonga (2001) observe the need for greater monitoring by the managers when firms are engaged in a highly competitive industry to safeguard the shareholders' interests. Information asymmetry can be reduced through disclosure decisions as it becomes a medium to monitor the actions of managers (Jensen & Meckling, 1976). Consequently, this disclosure would maximise the firm market value, and, thus, this may influence the variation of potential risks and uncertain information, where it also depends on the content of information and whether it carries good or bad news, the level of political costs and the opportunity for rivals to enter the market (Darrough & Stoughton, 1990). Following the above arguments, Alvarez et al. (2008) document the underlying reason for the positive impact of the industry concentration on voluntary disclosure that it is politically visible and that receives governmental support. In other words, the monopolistic position of firms due to their high concentration in a certain industry indicates greater incentive to provide more voluntary disclosure (Deegan & Carroll, 1993), and, thus, is reflected in the formulation of the following hypothesis:

H4: There is a significant positive relationship between industry concentration and risk reporting practices.

Leverage

Leveraged or high debt firms have been identified as preferring to disclose more information to satisfy the needs of various creditors (Alsaeed, 2006). Most likely, firms with higher debts in their capital structure are prone to higher monitoring costs (Jensen & Meckling, 1976) and are argued to be more willing to share their private information with the creditors (Robb et al., 2001). With the availability of such information for creditors in the public reports, there will be less hesitation in response to creditors' requests and claims (Wallace et al., 1994). It should be noted that the effects of leverage presented mixed findings. Belkaoui and Karpik (1987) prove the positive effect of leverage, while Meek, Roberts, and Gray (1995) found a negative impact of leverage on the level of voluntary disclosure.
However, most of the empirical studies have found an insignificant relationship between the high debts structured firms, which is likely to influence the variation in voluntary disclosure (Adamu, 2013). This might be due to the financing necessity of growing firms in emerging countries to provide adequate funding to finance their strategic projects for business expansion (Al-Shammari, 2014; Razek, 2014). The formulation of the following hypothesis:

H5: There is a significant negative relationship between leverage and risk reporting practices.

Methodology

Sample and data collection

The sample was drawn from 652 non-financial companies listed on the main Board of Bursa Malaysia for the financial year end 2006 to 2009. These four years are selected as it represents several years after the execution of the Malaysian Code of Corporate Governance (MCCG) in 2001. The research approach involves the content analysis of listed companies' published annual reports. Content analysis has been adopted in most of the prior research as it could capture the extent and volume of disclosure information, which is mainly reported in narrative statements with a quantitative nature (Deumes, 2008) and it also applies to corporate risk disclosure studies (Amran, Rosli, & Haat, 2009; Linsley & Shrives, 2006). In addition to the identified independent variables, this study includes the size of an organisation and industry affiliation as control variables (Elzahar & Hussainey, 2012). The definitions and measurements of variables used in this study are listed in Table 1.

Table 1: Definition and Measurement of Variables

Variable Acronym	Definition	Measurement
VRD	Quality of voluntary risk disclosure	Thematic analysis based on ICAEW risk categories
CAPINT	Capital Intensity	Ratio of the beginning-of-year net PPE to the fiscal year's average total assets
PROFIT	Profitability	Ratio of net profit to sales or revenue
REVGRW	Revenue Growth	Market to book ratio
INDCON	Industry Concentration	Herfindahl-Hirschman index – sum of the squared market shares of all firms in the industry
LEV	Leverage	Ratio of total liabilities to total assets
SIZE	Size of the company	Total assets

IND	Industry Affiliation	Environmental sensitive industry such as industrial, construction, plantation and properties. Score 1 if a firm belongs to environmental sensitive industry; 0 if otherwise

Risk reporting practices

Risk reporting practices is measured by the quality disclosure of voluntary risk information. An in-depth theme/topic-based analysis is used when reviewing such information reported in the annual reports. There are five themes/topics/items of non-financial risks based on Linsley and Shrives (2006). Then, the voluntary risk information will be grouped into three categories of quality measures based on studies by Beattie, McInnes and Fearnley (2004) and Abad, Bravo and Trombetta (2008). Each quality category has been identified with three or four levels of quality measurements. These categories are time orientation (forward looking/historical/not item specific), type of measurement (Quantitative measure; Extensive Descriptive/Quantitative measure; Brief Descriptive/Brief Descriptive/Obscure) and economic signs (positive/negative/ neutral).

Voluntary information regarding risk is reviewed using thematic analysis based on the risk categories recommended by AICPA (1998), the ICAEW (2002), and Linsley and Shrives (2006). Five themes are identified – operations risk, empowerment risk, information processing and technology risk, integrity risk and strategic risk. Narrative sections in annual reports such as Chairman's Statement, Review of Operations, Corporate Governance Statement, Risk Management Statement, Internal Control Statement, Corporate Social Responsibility and Sustainability Statement have been thoroughly reviewed. In order to capture the comprehensive or quality content of risk information, sentences are used as a unit of analysis and each of the sentences is classified according to the theme/topic, where the next phase is to assign a score according to its importance (Milne & Adler, 1999).

Analysis and Results

Descriptive statistics

Table 2 presents the descriptive statistics for the dependent variable, VRD and continuous independent and control variables. Results in Table 2 reported that the mean value for VRD is 211.30 sentences that contain pre-identified keywords as explained earlier. The minimum value is 18 sentences while the maximum value is 1133 sentences. This indicates that companies in the sample are disclosing more extensive voluntary risk information in their annual reports. Table 2 also reported that the mean values for CAPINT is 35.99%, PROFIT is 3.47%, REVGRW is 4.61%, INDCON is 45.26% and LEV is 76.38%. In relation to the control variables, the mean value for SIZE is RM2.12 million, while the mean value of IND is 0.55 percent.

Table 2: Descriptive Statistics of Dependent and Independent Variables

Variable	N	Min	Max	Mean	SD
VRD	652	18.00	1133.00	211.2929	182.40716
CAPINT	652	.17	91.95	35.9959	19.60932
PROFIT	652	-873.56	575.61	3.4683	58.17504
REVGRW	652	.12	214.53	4.6122	9.80648
INDCON	652	.00	2112.86	45.2586	191.87449
LEV	652	-3441.55	3068.70	76.3804	255.78199
SIZE	652	47196.00	103155492.00	2121362.9663	6223344.41059
IND	652	.00	1.00	.5460	.49826

Multivariate analysis

In this study, linear multiple regression is used as the basis of analysis for testing H1 to H3. The hypothesized relationships are modelled as follows.

$$VRD = \beta_0 + \beta_1 CAPINT + \beta_2 PROFIT + \beta_3 REVGRW + \beta_4 INDCON + \beta_5 LEV + \beta_6 SIZE + \beta_5 IND + \varepsilon$$

where variable definitions are given in Table 1.

In the above regression model, multicollinearity was tested using the variance inflation factor and tolerance levels and found to be well within the satisfactory range. The results of the regression analysis are presented in Table 3 and are now discussed in terms of tests of each of the hypotheses established in this study.

The selection of five business survivability mechanisms, namely: Capital Intensity (CAPINT), Profitability (PROFIT), Revenue Growth (REVGRW), Industry Concentration (INDCON) and Leverage (LEV). The use of these mechanisms is to justify possible signal elements contained in the information to examine the strength of such factors influencing the voluntary risk disclosure decisions by the managers.

The results from Table 3 indicates survivability variables are significant in the model, whereby it is useful to predict possible effects on voluntary risk disclosure from 2006 to 2009. The explanatory power (R2=0.431) of the model indicates the independent variables have an impact on overall model (p <.000).

Table 3: Multiple Regression Results

DV : Voluntary Risk Disclosure			
R^2	0.431		
Adjusted R^2	0.423

* significant at 10% (2-tailed)
** significant at 5% (2-tailed)
*** significant at 1% (2-tailed)

Results attained for Hypotheses H1 and H2 reveal that the relationships between the effects of capital intensity and profitability toward voluntary risk disclosure are found to be insignificantly influenced to each other from 2006 to 2009. This implies that companies that possess better firm performance in order to prevent the entrance of competitors to the existing market did not have any influence on the management variation decisions of voluntary risk disclosure. Moreover, the notion of unfavourable

information would be hidden from the public may justify the decision made by the management (Das et al., 2015).

Conversely, hypotheses H3 to H5 have observed with significant influence on voluntary risk disclosure. The finding for revenue growth signal indicates a significant result which suggests that a high percentage of revenue growth will lower the voluntary risk disclosure. This is inconsistent with Darus at al. (2008) who found insignificant results between these two variables. It was argued that the growth information of companies did provide a potential signal to create a competitive disadvantage for the firm. In addition, growing firms may give greater attention to providing more voluntary risk information to avoid misinterpretation or false rumours of such information that probably relates to other internal development (i.e. human resource, products, etc.), which would consequently affect their visibility and reputation among other market participants (Iatridis, 2008).

In similar vein, the result for industry concentration shows a positive significant relationship with voluntary risk disclosure indicating larger industry concentration will lead to greater voluntary risk disclosure. Consistent with Iatridis (2008), it was emphasised that firms were willing to provide comprehensive disclosure when they had experienced higher performance to impress investors and other market participants in approving their actions. Since this measurement is the indicator for industry competitiveness, hence firms assessed as having a large industry market share tend to have more incentive to disclose extensive voluntary risk information to reduce information asymmetry between the shareholders and firms' management (Harris, 1998; Haw et al., 2015) and to deter competitors from entering the existing market (Darrough and Stoughton, 1990).

In addition, with regards to leverage, the result suggests that high leverage firms would be having more interest in providing more voluntary risk disclosure indicating that more voluntary disclosure would be reported for high leverage companies. This is due to close monitoring by debt providers who have an expectation of ongoing reports to be submitted pertaining to the financial status as well as the risk and unanticipated events that could affect the financial commitment, especially in the period of crisis (Mukherjee et al., 2010; Purushothaman, Tower, Hancock, & Taplin, 2000).

Conclusion

This study provides insights into the impacts of business survivability mechanisms on risk reporting practices. The findings revealed that there were significant influence of survivability mechanisms such as revenue growth, industry concentration and leverage; on risk reporting practices. This confirmed that larger firms, signified by the larger capital intensity, have a substantial influence on the variation of risk reporting practices (Das et al., 2015; Elzahar et al., 2015; Iatridis, 2008), which would eventually be a discouragement to the competitors to enter the existing market (Darrough & Stoughton, 1990). In particular, the Malaysian PLCs have shown greater willingness in providing more information regarding risk and uncertainty to minimise the potential detrimental effects as well as to differentiate themselves from poor performing companies. Although the information is believed to be manipulated by the competitors, companies are evidenced to perform better than the competitors. Several reasons underlie the decisions made by the management as to ensure business survival: to signal companies' performance for the decisions' betterment purposes. Secondly, is to raise share prices resulting from the disclosure of favourable information. Nevertheless, the ground reason might relate to business strategy to create competitive advantage; whereby they could distinguish themselves from other ordinary companies. Apparently, the competitive contents in those information provide incentives for management in deciding on which is the best approach to disseminate information voluntarily to relevant parties.

This study also recommends further insights on the ability of forward-looking information to signal the management decisions in years after the introduction of the MCCG. This study is limited with regard to the measurement of risk reporting practices, which was based on recommendations made by several

practitioners through interview sessions conducted in the initial stage of the study. However, the opinions of other parties, such as the analysts and the community were not acquired due to limited scope and time. Thus, the generalisation of these new items is subject to these limited sources. Future research may take this into consideration.

Fighting Counterfeiting: Understanding the Determinants of Trademark Counterfeiting and Its Economic and Social Impacts

Khadijah Mohamed, Senior Lecturer, School of Law, Universiti Utara Malaysia, Malaysia
Currently an academic visitor, School of Law, University of Glasgow, United Kingdom
khadijah.mohamed@glasgow.ac.uk; khadijah@uum.edu.my

Abstract

This study examines the determinants of the global growth in trademark counterfeiting and relates how this activity could result in significant negative effects on legitimate businesses, governments and consumers. The aim is to assist the businesses and relevant authorities in determining appropriate action to effectively deal with the problem. The study adopts qualitative approach as a tool for data collection in identifying the scale of counterfeiting and employs legal approach to analyse the provision of relevant laws. The study identifies few interconnected leading factors triggering the widespread of counterfeiting to include: huge profit with low risk of criminal sanction, weaknesses of legal system, globalization of businesses and technological advances. Counterfeiting harms relevant stakeholders in many ways: diminishing legitimate businesses' reputation, depriving governments' revenue and endangering consumers' health and safety. The study finds that the extent, scope and negative impacts of counterfeiting cry for effective enforcement. The study also identifies some important learning points for policy makers and recommends that the enforcement mechanisms used should have a deterrent effect against counterfeiters. This may include the availability of criminal enforcement and sanctions to deter further violation plus effective remedies to the injured parties in ensuring sustainability of legitimate businesses in developing national economies as well as protecting consumers from any anticipated further harm. It is also recommended that further analysis can be conducted on how joint efforts by government agencies and industry may yield better result to enhance the effectiveness of enforcement efforts in fighting counterfeiting.

Keywords: counterfeiting, determinants, economic and social impacts

Introduction

In recent years, intellectual property (IP) intensive activity has grown as a leading contributor to the economic success of many nations, both in terms of jobs and value added to Gross Domestic Product (GDP) (Oswald and Pagnattaro, 2015). A research shows that about 70% to 80% of a company's market capitalization comes in the form of intangible assets, which include IP rights (IPRs) assets such as patents, trademarks, copyrights, and other business knowledge and know-how (Hadzima, 2013).

In the European Union (EU) for instance, IPRs-intensive industries contribute almost 26% of employment and 39% of GDP during the period 2008-2010, with almost 21% in trade mark-intensive industries compared to other types of IPRs such as patent, design and copyright (EPO and OHIM, 2013). Similarly, in the United States (US), IPRs-intensive industries directly accounted for 18.8% of all employment and 34.8% of US GDP in 2010 with a substantial share of trademark-intensive industries with 22.6 million jobs followed by patent (3.9 million jobs) and copyright-intensive industries (5.1 million jobs) (US Patent and Trademark Office, 2012).

Obviously, trademarks become the most widely used form of registered IP throughout the world (WIPO, 2013) to protect and support businesses' branding activities for the goods and services they market. In fact, trademarks have been used in commerce since hundreds of years to identify and distinguish the source of goods or services of one party from those of others. This prominent function of trademarks allows not only the consumers to know and detect who supplied or manufactured goods, but also helps the businesses to establish and protect their goodwill and reputation. In *Arsenal*

Football Club Plc v Matthew Reed [2003] Ch.454 for instance, Advocate General Ruiz-Jarabo Colomer re-emphasised this function and observed that:

> "The trademark acquires a life of its own, making a statement, as I have suggested, about quality, reputation and even, in certain cases, a way of seeing life".

Trademarks therefore play an important role in conveying reliable information to consumers about the quality of goods and the manufacturer's reputation. However, these important benefits may be destroyed by counterfeiting activity.

The term counterfeiting in the context of IP is generally used where illicitly produced goods infringe existing protected trademark rights. Article 51 Footnote 14 (a) of the Trade Related Aspects of Intellectual Property Rights (TRIPS) Agreement provides that "counterfeit trademark goods" shall mean any goods, including packaging, bearing without authorization a trademark which is identical to the trademark validly registered in respect of such goods, or which cannot be distinguished in its essential aspects from such a trademark, and which thereby infringes the rights of the owner of the trademark in question, under the law of the country of importation. In fact, various studies have identified trademarks as the most frequent violated rights among other types of IPRs (OECD, 2008; ICC-BASCAP, 2011; Mohamed, 2012; JPO, 2015; EC, 2015; USCBP, 2015 WCO, 2015).

Counterfeiting activity can be traced back to be as ancient as the practice of marking goods among traders. Soon after products acquire a reputation in the marketplace, others will try to imitate and gain profit without much effort. In recent years, counterfeiting even becoming one of the fastest growing economic crimes despite the fact that most countries, particularly the World Trade Organization (WTO) members, have adopted necessary legislation into their domestic laws which among others, intended to address the problem (Wadlow, 2007, p.353; Mohamed, 2012, p.5).

What is the main reason for this problem? Why counterfeiting remains rife while all necessary legislations are already in place? In responding to these questions, this paper argues that there is significant need to study the underlying problems of counterfeiting and how its global prevalence and impacts may be used for the attention of relevant authorities. This paper attempts to examine the determinants of the global growth in trademark counterfeiting and relates how it could result in significant negative impacts on legitimate businesses, governments and consumers. Since IPRs had an important effect on economic value of a nation especially in terms of jobs and value added to GDP (Idris, 2003, p.3; Hadzima, 2013; Oswald and Pagnattaro, 2015), their creation, exploitation, and protection are therefore increasing importance. Thus, identifying the determinants and impacts of counterfeiting is crucial for the businesses and relevant authorities in determining the appropriate action to effectively deal with it.

Research Methodology

This study employs socio-legal method; the study of law which relates to social phenomena and adopts methods from the social sciences, either qualitative or quantitative research approaches to obtain some kind of empirical data in collecting the relevant data. Wheeler and Thomas (2002, p.271) indicate that the "socio" in this context does not refer to sociology or social sciences, but represents "an interface with a context within which law exists".

The aim of collecting empirical data is to provide vital insights from an external perspective into how the law works in society because the aim of this study is to examine the scale of trademark counterfeiting and how legal measures may be used to effectively deal with it. The scale of counterfeiting is derived from the seizure data issued by the World Customs Organization (WCO) emphasizing on the worldwide scenario which is discussed in greater detail below.

Thus, the use of social theory for the purpose of analysis in legal research most often tends to address the concerns of law and legal studies as stressed by Yaqin (2007, p.13) that "where the true factors for the emergence or existence of a problem or issue are identified by empirical inquiry, law, where it is applied and enforced with the necessary will, commitment and appropriate strategies, can serve as an effective mechanism of control, regulation, change and reform".

Examination on the scale of trademark counterfeiting

The illicit nature of counterfeiting makes it difficult to quantify precise data either on the extent of the phenomenon or the impacts it caused to the parties involved. Hence, several limitations of this study need to be acknowledged. There are many studies investigating the problem from different views and the relevant range of data sources in this regard may be classified into three main categories: enforcement and judicial agencies, companies and industry bodies and economic impact studies by research consultancies, each with their strengths and weaknesses (Mohamed, 2012, p.50).

While data from industry and research consultancy provide significant insights, criticism for being biased particularly for the purpose of lobbying authorities cannot be avoided (Correa, 2009, p.31). Meanwhile, data from the customs (enforcement) authorities may be understated as the estimated figures are only based on reported cases. However, when the customs data is corroborated against background information from industry and research consultancy, this may catch trends missed by customs data.

In this study, the data used is mainly based on seizures by customs or enforcement agencies which supported by reports from other sources to be used as a rough measure in comparing and identifying trends in the development of counterfeiting phenomena. The data is also supplemented and corroborated by interviews with key figures among the official, judicial and practitioner sectors in IP field. Although the data used is selective, it serves the purpose of this study to reveal the scope and extent of counterfeiting.

Based on the reported seizures provided by the WCO, counterfeiting activities can be summarized as in Table 1 below, which provides significant insights on the growing trend of its worldwide phenomena.

Table 1: WCO Regional Data on IPRs Detentions by Number of Cases

Number of IPRs Seizures Cases								
Year	**2007**	**2008**	**2009**	**2010**	**2011**	**2012**	**2013**	**2014**
Cases	8,416	14,981	21,940	27,606	20,932	22,543	25,032	21,930

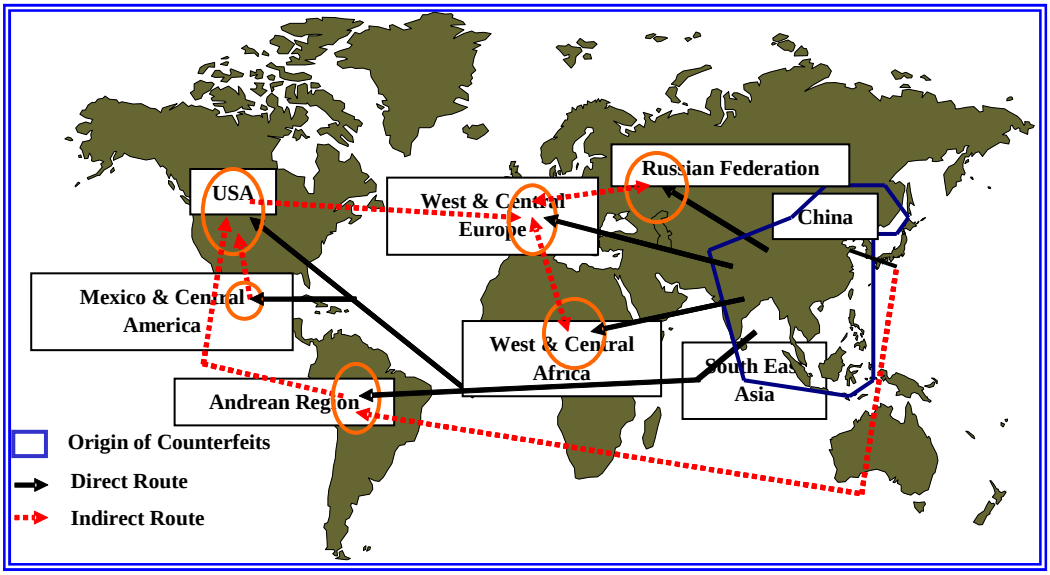
Note: The seizure cases for 2007-2011 were based on 10 WCO RILO regions consisting of Western Europe, North America, Asia/Pacific, CIS Region, Eastern & Central Europe, South America, Eastern & Southern Africa, Middle East, North Africa and West Africa. For 2012-2014, the cases were based on WCO CEN inputs of 58, 69 and 63 member countries in 2012, 2013 and 2014 respectively.

This data is based on the results submitted by members to the Customs Enforcement Network (CEN), a reporting framework developed by customs agencies through the WCO. Seizures data contained in CEN had been entered and validated by the WCO Members and the eleven Regional Intelligence Liaison Offices (RILOs) (WCO, 2015).

It is worth to note that while the data might be affected by level of notification thus possibly rendering them incomplete and should be taken with caution, they however underscore a remarkable increase. In fact, the trend showed in WCO data matching with seizures statistics from other authorities in the IP-developed nations such as the EU, Japan and the US (JPO, 2015; EC, 2015; US CBP, 2015) and also other previous reports (OECD, 2008; Chaudhry and Zimmerman, 2009, p.11; Treverton *et.al*, 2009, p.3; ICC-BASCAP, 2011) indicating the rampant of counterfeiting in virtually all economies.

Notably, almost all reports indicated China to be by far the main country of provenance from where goods suspected of infringing IPRs were sent to other parts of the world. While Asia is identified as the main source of counterfeit goods, other regions also play a role either as destination markets or as transit hubs in distributing such goods as shown in Table 2 below.

Table 2: Distribution Route of Global Counterfeiting



Some other countries are also appearing as the main country of provenance for specific product categories. For example, Malaysia is identified by the EU Customs in 2014 as one of the provenance countries for packaging materials from where infringing IPRs goods were sent to the EU (EC, 2015) while in 2015, the United States Trade Representative (USTR) reported that media box-based piracy, whereby storage devices are loaded with large quantities of pirated works is growing in popularity in Malaysia together with a few other countries (USTR, 2015).

The finding, while tentative, suggests that counterfeiting will continue to increase for a relatively long period. This development indirectly confirms the value of IP in driving the economic growth of a country (Bird, 2009; Mengistie, 2010; Oswald and Pagnattaro, 2015; OHIM, 2015).

Determinants of counterfeiting activity

While there are many motivating factors behind counterfeiting activity, commentators however classified the following as the most interconnected prominent ones (UNICRI, 2007; OECD, 2008; Treverton *et.al*., 2009; Chaudhry and Zimmerman, 2009; ICC-BASCAP, 2011):

(a) high profit with low risk of criminal sanction;
(b) weaknesses in the legal system;
(c) globalization of businesses; and
(d) development in technological advances.

High Profit with Low Risk of Criminal Sanction

People involve in any illicit activities normally aim for quick and huge profits. Likewise, several studies found that high profits and ineffective legal enforcement have become the prime reasons for the growth of counterfeiting (Anderson, 1999, p.56; Phillips, 2005, p.3-4; Treverton *et.al*, 2009, p.4). This is not surprising given the fact that production cost of counterfeit goods is rationally low

because counterfeiters do not bear costs as those incurred by trademark owners in developing, marketing and establishing their products and reputation plus providing after-sale customer services. This means, counterfeiters operate at a very low cost with great margin as they can avoid many risks and overheads that legitimate businesses must take (Defer, 1999, p.54).

Numerous studies also revealed that enormous profit margins from counterfeiting are so convincing, and sometimes might even match or exceed those from drug trafficking (Hetzer, 2002, p.303; Treverton *et.al*, 2009, p.4; UNIFAB, 2016). In Europe for instance, a kilo of cannabis could be sold for up to €2000, while a kilo of counterfeit CDs could reach €3,000 euros (UNIFAB, 2016, p.22). In contrast, the nature of counterfeiting offences compared to other type of crimes including drug-related offences is considered as having a low risk of penalties (Kuala Lumpur IP Sessions Court Judge, 2009) with only few years of imprisonment contrasting with life imprisonment for drug-related offences in many countries. Such a gap between huge profits with relatively low risks of penalty would certainly attract those involved in illegal activities to engage in this kind of business. Thus, if no effective measures to be taken by the authorities, it is argued that the trade in counterfeiting will remain rampant.

Weaknesses in the Legal System

Several studies recognized that weaknesses in IP legal system do not necessarily stem from a lack of existing substantive law or the complete absence of law, but might relate to how the law is enforced (Breitkreuz, 2007; Treverton *et.al*, 2009, p.129; UNIFAB, 2016, p.20). In some cases, IPRs enforcement has been given a relatively low priority with less resources from governments that leads to situations where enforcement officers have lack of power to arrest or they do not be equipped with appropriate weapons for self-protection when conducting raids (Vagg and Harris, 2000, p.109; Phillips, 2005, p.132; Yar, 2005, p.19; OECD, 2008, p.26; Officers of MDTCC, 2009). Further constraints include the difficulty of prosecution and legal proceedings and also the non-deterrent penalties, as mentioned earlier. All these factors encourage counterfeiters to exploit the shortcomings of IP enforcement and legal loopholes across jurisdictions to escape authorities.

Globalization of Business

With openness in trade, finance, travel and communication, globalization creates massive opportunities for businesses to prosper through collaboration among multiple organizations, people and teams working in different parts of the world (Mohamed, 2012, p.192). The same benefit is shared by counterfeiters whose activities flourish across borders. Particularly, the advantages of free trade zones and free ports provide them with safe venues for the "transshipment" of counterfeit goods. Although transshipment is normally legitimate as part of the world's trade (Chaudhry and Zimmerman, 2009, p.21; Murphy and Wood, 2008, p.144; Kim and Gunther, 2007, p.3), the technique is unfortunately being widely used by professional infringers as a tactic to outwit customs authorities (Bonadio, 2008, p.81; Godart, 2010, p.382; Engels, 2010, p.2).

Technological Advances

The rise of digital technologies has irrevocably transformed the global economy by revolutionising modes of production, distribution and innovation (Gibert, 2015). Devices such as laser printers, copiers, or reprographics could help almost anyone who has access to these types of technologies to possibly produce high quality forgeries at a very low cost (Suthersanen, 2006, p.231). The Internet in particular, is becoming an increasingly important vehicle for selling goods and significantly has aided counterfeiters with an instantaneous worldwide market. In some cases, counterfeiters even establish legitimate looking websites to sell counterfeit goods (Markovic, 2008, p.183; Bain, 2011), leaving enforcement authorities with permanent challenge to acquire and maintain the necessary technological expertise.

The Impacts of Counterfeiting

In assessing and justifying the appropriate action(s) for fighting counterfeiting, it is essential to consider the impact of counterfeiting on the parties, directly or indirectly involved in this problem. Based on the extent of the problem discussed earlier, counterfeiting is believed becoming a global challenge that affects businesses, consumers and governments. Its impacts therefore are both; economic and social.

Economic

The economic impact can be classified as either direct or indirect. Business proprietors will experience a direct impact where counterfeiting could undermine their business competitiveness through the loss of profit and deterioration of the quality and value of their trademark. This leads to a significant indirect impact when counterfeiting could also possibly destroy honest jobs, thus affecting the revenues of governments, foreign investment, trade and innovation and threatening the health and safety of consumers (Nia and Zaichkowsky, 2000, p.485; OECD, 2008; ICC-BASCAP, 2011).

Measuring the number of losses from counterfeiting is as much difficult as quantifying its scale. However, based on WCO seizure data suggesting the scale of counterfeiting is expanding, the same could be anticipated on the losses. For example, in 2011, the International Chamber of Commerce indicates that the global economic and social impacts of counterfeiting and piracy will reach USD1.7 trillion by 2015 (ICC-BASCAP, 2011). This showed a significant increase from an OECD report in 2008 estimated the upward trend of counterfeit goods in international trade could have amounted to a value of up to USD250 billion (OECD, 2008; ICC-BASCAP, 2011).

Social

The negative consequences of counterfeiting also affect consumers and governments. Few reports indicated that counterfeiting causes job losses from IP industry sectors that employ millions of people around the world. For instance, it was estimated in 2007 that more than 100,000 jobs are lost every year in the EU countries and about 750,000 in the US on account of counterfeiting (UNICRI, 2007, p.6) while ICC-BASCAP (2011) predicts that approximately 2.5 million jobs have been destroyed by counterfeiting and piracy every year in the legitimate economies of the G20 countries. The Japan Patent Office (2015) also reported that in 2013 alone, about 22% of Japanese companies are suffering from damage caused by counterfeiting, up by 0.2% from 21.8% in the previous year.

Consumer Health and Safety Issues

The expansion of counterfeiting into new product categories has also put greater risk to consumers. Recent focus of counterfeit goods which has shifted from luxury goods to all kinds of consumer goods, including foodstuff and pharmaceuticals, exposing consumers to significant health and safety risks (Mohamed, 2012, p.69) as they are unlikely to have been subjected to the rigorous quality control that is required with genuine products (Prendergast *et.al*, 2002, p.406). For instance, in 2006, a £9 counterfeit charger had electrocuted and caused death of a 7-year-old boy of Walworth, South East London during a family holiday in Phuket, Thailand (Mohamed, 2012, p.1) while in 2003, the investigators of the Norwegian plane crash in 1989 which killed 55 people revealed that substandard counterfeit bolts and sleeves of an unknown origin had partly caused the incident (IACC, 2005).

While this kind of incidents would certainly harm consumers, in the long run it will actually undermine consumer confidence in established brands and trademarks. This is because, the poor quality of counterfeit products and their confusion with genuine products will lead to a deterioration of the rights-holders' or manufacturers' image (Prendergast *et.al*, 2002, p.406). Thus, counterfeiting in this context could both risk the consumers' health and safety as well as harm the rights-holders' economic gain.

Organized Crime

Another serious impact of counterfeiting is the involvement of other aspects of organized crime, where counterfeiters may use the profits from counterfeiting for other unlawful activities such as terrorism and money laundering (IACC, 2005; UNICRI, 2007; OECD, 2008; Pollinger, 2008; ICTSD, 2009; UNIFAB, 2016, p.6). This may encourage counterfeiting business becoming more pervasive, thus affecting health and safety issues as well as creating social problems. In view of this, effective enforcement is critical to deal with trademark counterfeiting.

Discussion, Limitation and Recommendation

The data presented in this study confirms that there is an increasing trend and scale of counterfeiting, consistent with most of the previous reports on this subject. The study then examines how industries and legitimate businesses, governments, employees and consumers representing the public at large are affected by counterfeiting. The study found that the trend of counterfeiting is also expected to remain prevalent for a relatively long time, and the problem does not appear to be limited to particular product types or the luxury sector, but is quite general. Thus, serious attention from the enforcement authorities is necessary to address the problem.

The study also found that, competent IP legal system is crucial in fighting counterfeiting. It requires both the enactment of appropriate legislation and the effective enforcement of rights. The study recognised that the weakness in the IP legal system is actually found in a combination of these elements, thus contributing to the increasing trend of counterfeiting despite most WTO member countries already having implemented the necessary legislation that conform to at least the minimum standards of the TRIPS Agreement. The study argued that since there is a direct connection between the enforcement regime and the prevalence of counterfeiting activities, it is recommended that governments should immediately address the flaws in this area by improving the enforcement capacity and allocating sufficient resources.

Improvements in enforcement may include continuous training for enforcement officers in the abilities of the investigating and prosecuting officers, so that they may have the necessary expertise or knowledge of the technical issues that is necessary in pursuing a case. The improvement in this area will benefit the country economically in the long run, as successful prosecution and imprisonment not only serve as a useful deterrent for future behaviour, but also send out the right message to investors on the competent legal system in protecting their rights.

It is also recommended that expeditious remedies should also be available to the injured parties such as injunctions, compensation for damages, orders to destroy infringing products, provisional measures to seize infringing products and secure evidence, border measures by customs authorities, and the availability of criminal enforcement and sanctions. Allocating adequate resources is also necessary particularly in increasing the numbers and expertise of enforcement officers. This is because criminal conviction requires a thorough and complete process from the investigation stage through to prosecution.

Thus, the findings of this study are intended to provide policymakers with an effective available enforcement framework without resulting in drastic structural changes, yet conforming to international standards. Proper implementation and effective enforcement not only assist the country in question by meeting international requirements, but importantly, benefit the public at large as they will be better protected from the risk caused by counterfeit goods.

It is also worth to note that, given the illicit nature of counterfeiting, these results must be interpreted with care as they may not constitute conclusive proof on the problem. While this study has helped to improve our understanding on the determinants and impacts of counterfeiting within business environment, certain scope remains for further research by using the data compiled for this study.

For example, further analysis can be conducted on how joint efforts by government agencies and industry may yield better result to enhance the effectiveness of enforcement efforts. It is recommended that consistent enforcement from all relevant authorities that strengthens their co-operation at all levels must be improved by providing appropriate training to the officers and sharing information and intelligence with industry. Competency of officers and collaboration with industry will be necessary in order to achieve success in fighting counterfeiting.

Conclusion

The massive infiltration of counterfeiting harms many aspects of life – from businesses whose goods are counterfeited, to governments and to the public as a whole. With many factors to provide a good environment for its growth, counterfeiting has evolved into a much more lucrative business in very sophisticated ways. While there are many contributing factors to its proliferation in recent years, this paper argues that the only real area where the government can make a difference is in setting up a responsive legal system that includes good enforcement.

Since there is a direct relationship between the strength of the enforcement regime and the prevalence of counterfeiting activities, it is argued that more attention should be given by the relevant authorities to this matter. It is believed that the stronger the enforcement, the less likelihood there is of counterfeit goods to be on the market. Hence, factors which are likely to hinder this process must be identified and addressed. Weaknesses in enforcement capacity and resources must be addressed immediately. This is to ensure that the enforcement mechanisms used will have a deterrent effect against counterfeiters and at the same time assuring protection to all the parties concerned. Protection in this context may include effective remedies to the injured parties such as compensation for damages, injunction orders by courts for infringement, border measures by customs authorities, and the availability of criminal enforcement and sanctions. Such effective enforcement of IPRs is a matter of crucial importance and relevance to all countries in addressing the endemic of counterfeiting.

The Causal Relationship between the Housing and Labor Mobility

Daniela Spirkova, Slovak University of Technology in Bratislava, Slovakia,
daniela.spirkova@stuba.sk
Csilla Fulopova, Slovak University of Technology in Bratislava, Slovakia, csilla.fulopova@stuba.sk

Abstract

The housing market, similar as the labor market is regionally and structurally differentiated in every country. Since the human capital itself is not homogeneous, a mutual discontinuity occurs. Consistency between housing (with emphasis on rental housing) and jobs (labor market) in several developed economies has become an important part of state public policy and local governments. The problem of Slovakia in the sphere of labor mobility needs to be taken from several angles. First, in significantly lower proportion of rental housing (including social rental housing) and also the low regional mobility. The article discusses the problems and the causal relationship between the housing market and labor mobility in Slovakia.

Keywords: Housing market, Labor market, Labor mobility, Rental housing in Slovakia

Introduction

Housing need and its solution is determined by several interconnected factors. The demand determining factor on the side of the housing market is demographic development of the population from which the need for housing is objectively derived. The real demand for housing is largely dependent on social-economic status of potential applicants for housing and their current and expected financial situation. From that are subsequently derived activities of investors and developers who create a certain supply of housing. Demand and supply side of the housing market is influenced by the state housing policy, which should create a framework for harmonization of these two sides. State housing policy generally reflects some well-established national practices but should also respond to current issues and needs for sustainable socio-economic development of society. In this meaning, in recent years Slovakia receives recommendations of the various relevant international institutions towards more assistance for rental housing in order to increase labor mobility (Car, 2014). Housing is therefore an important source of employment. The functioning of the housing market is connected with the mobility of housing, which is closely linked with the desired and undesired labor mobility. Many people have become "prisoners" of their homes, whether rented or own housing due to lack of offers or for economic reasons. Requirement of ensuring increased mobility of housing is a prerequisite for greater labor mobility and thus better opportunities and success in the labor market. In order to ensure the competitiveness of regions and foster job mobility, it is necessary to diversify the supply of housing - not only at the level of different types of ownership and usage, but also diversity in the supply cost to provide housing. The reason is particularly the availability of quality housing, which will proportionally correspond with the financial resources of households. Also instant availability of housing for employees is an essential condition for the development of a dynamic labor market - the development of employment is blocked by the lack of housing (see also Spirkova, Zubkova and Stehlikova, 2015).

Demand for housing is significantly higher in those areas of Slovakia which provide more job opportunities which can be, based on economic and social parameters, considered as more advanced. For example due to the currently implemented mega-investment Jaguar Land Rover in Slovakia, the pressure on prices of flats in the region of Nitra has increased. The arrival of the new investor makes from the surrounding of Nitra a lucrative locality which greatly contributed to an increase of apartment prices about 10 to 15 percent, in some cases up to 20 percent in comparison with the end of 2015.

Despite significant regional differences in unemployment levels (see Fig1), regional mobility of labor in Slovakia is relatively low and limits allocation of available job opportunities to suitable job applications. Slovak labor market has one of the lowest fluctuations of the labor force in the EU, which is also caused by low internal geographical labor mobility (EC, 2015) (see Fig. 2 - we have obtained available data until 2009, new data for 2010-2015 are currently being processed).

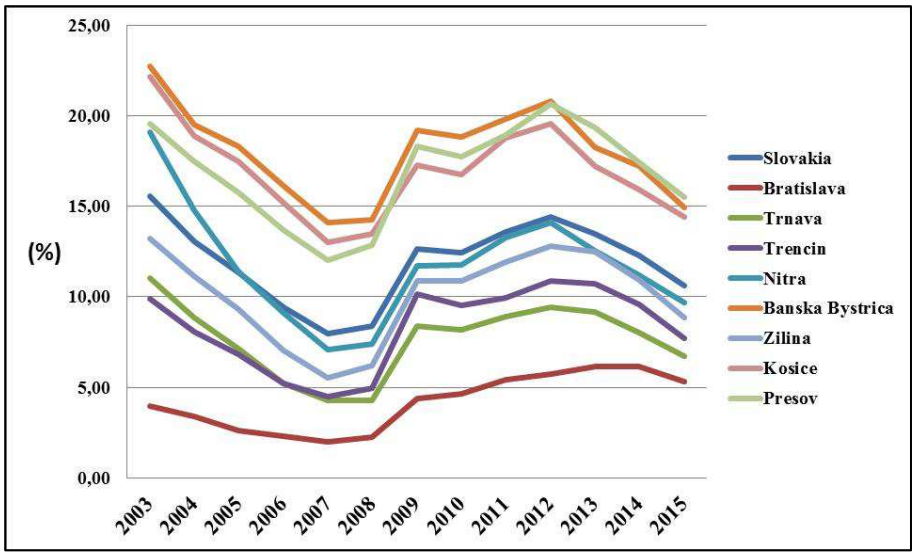

Fig. 1 Unemployment rate in the Slovakia by regions and years (%)
Source: Statistical Office of the Slovak Republic

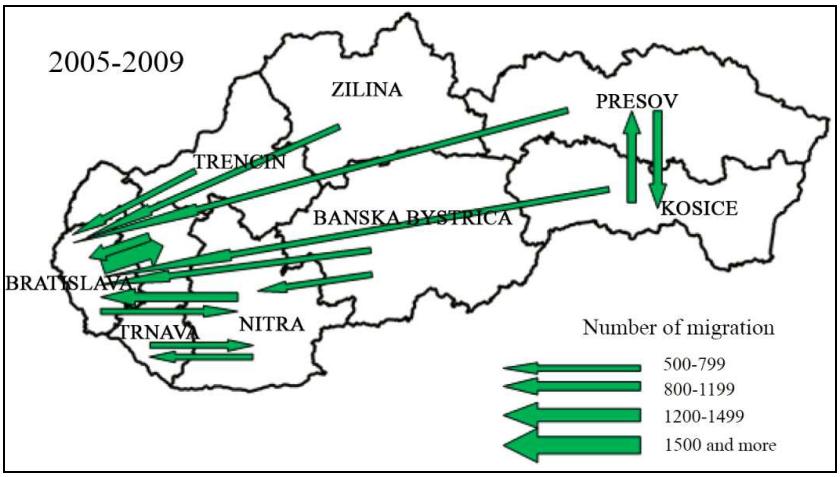

Fig. 2 The main migration flows between regions of Slovakia (number of transfer)
Source: INFOSTAT, Slovak Republic, 2010

Some of the factors hindering mobility are insufficient transport infrastructure, high transport fee and accommodation costs as well as underdeveloped market with rental housing. For example, in 2011 in Slovakia, only a very small population of working age (15-64 years) changed place of residence, with only 3% of those who moved, the reason of moving was linked to employment. The number of available rental housing in Slovakia is generally low, and access to social rental housing belongs to the lowest in the EU (see Fig. 3).

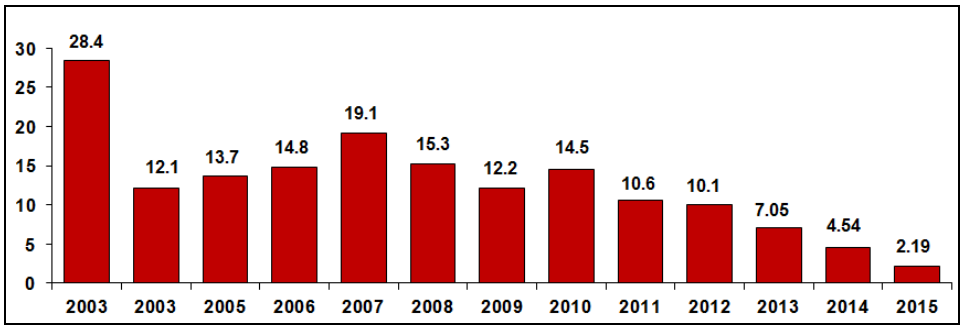

Fig. 3 Evolution of share of rental apartments in Slovakia among the total number of completed apartments (in %)

Source: own processing according to data from the Statistical Office of Slovak Republic

Important is also the fact that social rental housing depends on income. This means that in case of entitlement of rented apartment, the motivation to earn more money is lower. The reason is the fear that the tenant loses his entitlement to a rented flat. The result of such a situation is reduced incentives to work and thereby decrease the mobility of labor. On the other side, the second extreme in Slovakia is a high proportion of persons who have apartments in their ownership. Purchase, respectively rental of residential property is generally not just a matter of rational economic calculation, but to some extent it is also a reflection of national usage. Within the internationally comparable survey on income and living conditions (Statistics of Income and Living Conditions - SILC) in European countries is proven that not only in Slovakia but also in most countries is ownership of the house or apartment preferred more than rent. In the EU 28, 70% of the population subscribes to the ownership of residential property. However, between countries are obvious differences. Slovakia clearly belongs to the category of countries where the term ownership of real estate considerably resonates (up nearly 90%). On the other hand, the most significant relationship to the rental housing in Europe is shown by people of Germany and Austria.

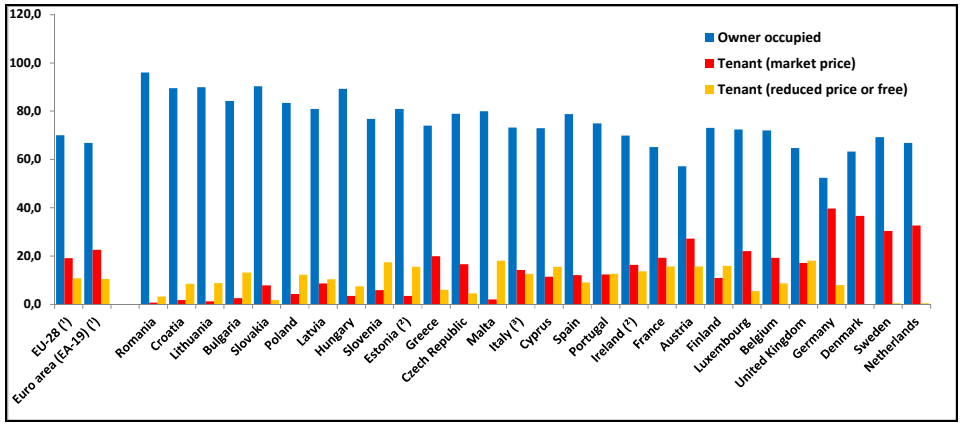

Fig. 4 Distribution of population by tenure status, 2014 (% of population)

Source: own processing according to EUROSTAT data

Based on data from Eurostat, we can assume that in 2014 up to 70.1% people in the EU-28 lived in an owner-occupied home, while 19.1% were tenants with a market price rent, and 10.8% were tenants in reduced-rent or free accommodation. More than a half of the population in each EU Member State (see Fig. 4) lived in owner-occupied dwellings in 2014, ranging from 52.4 % in Germany up to 96.1 % in Romania. As such, none of the EU Member States recorded a share of tenants that was higher than the share of people living in owner-occupied dwellings.

Theoretical basis and Methodology

The housing market is one of the structural factors impacting the regional mobility of labor. Consistency between housing (housing market) and jobs (labor market) in several developed economies has become an important part of the public policy of the state and local governments. There are several reasons why housing affordability is increasingly linked to the availability of jobs: improving the quality of life through better access to work, education and services, corporate demand for workers living in the vicinity, solving traffic problems (high travel costs, etc.), environmental protection, efficient use of land resources etc. As reported by Cervero (1989), answer to this discrepancy can be so called balance of housing and work policy (job and housing balance policy). Based on the theoretical assumption that the ideal balance between jobs and housing leads to higher efficiency, equity, quality of life and environmental sustainability. Measures of balance work and housing policy do not have purely residential nature, but rather operate in synergy with other policies, especially social protection, labor market and transport policy.

In Slovakia, the real estate market is characterized by a high proportion of owner-occupied real estates and almost non-existent rental housing. Moving for work is therefore complicated because of lacking availability of rental housing. The current structure of the housing market is largely due to historical development - both in the development before 1989 as well as the lack of adaptation of the housing sector to the new conditions in recent decades. After the change of political system in 1990, the transformation process began, which also included the privatization process. Part of the privatization process in 1992 was the introduction of the right to redeem the property for tenants in state apartments at very reasonable prices (apartments were redeemed into private property at prices that correspond to 5% of their market value), resulting in a change in ownership structure. A large proportion of public rental housing was subsequently purchased by tenants into the private sector. For example in Bratislava, the share of private housing increased from 12% in 1992 to 70% in 1998. Apart from the historical context, the main factors and reasons why housing sector limited mobility may include long-term development of the housing market and the structure of the use of apartments (Vagac, 2003). High occupation of flats, the rise of prices and rents, geographic differentiation of wages etc. leads to the reduced labor mobility. While the historical development has helped to shape the current structure of housing, housing support policy helps to preserve this structure and thus contributing to the slower development of rental housing. At present, most public expenditure spent on housing support is used for subsidy of owner-occupied housing. Cheaper financing of owner-occupied housing has direct impact on the entire housing market. Subsidized owner-occupied housing is financially more attractive and more accessible than rental housing. This promotes the demand for owner-occupied housing at the expense of rental housing. Market reacts to lower demand for rental housing with lower investments into creation of new rental housing, which leads to slower development of this segment of market.

Flexible labor market enables workers the better choice of employment and the efficient allocation of labor among companies. In Slovakia, one of the obstacles of labor mobility in the labor market is low regional mobility. Compared internationally, Slovaks move for work much less than people in neighboring EU countries. One of the factors that may negatively influence this condition of the labor market is the housing market. Low mobility on the labor market has a negative impact on economic growth. Regional unemployment is rising while jobs remain unoccupied. The low labor mobility also reflects regional differences in unemployment rates. It leads to inefficient use and allocation of human resources. People are forced to refuse job opportunities in other regions, where they could generate more economic value and thus earn more money. Higher unemployment and limiting productivity growth are associated with lower GDP and lower living standard. Labor mobility involves changes in the physical location of workers (geographical mobility) or their movement across jobs and sectors (occupational mobility). Two main types of internal labor mobility are in the center of attention - internal migration and commuting. Migration is usually associated with a change in the residence of a worker (in economic literature, a migrant is considered a person who stays in the destination region for more than one year). Commuting occurs as a rule without a change in a

worker's residence (i.e. a worker's place of work and place of residence are located in two different regions) (Vagac, 2013).

Available cross-country comparisons show that mobility flows in Slovakia are low in international terms. This applies in particular to internal migration, which means to flows connected with a change in the place of residence. The internal migration rate for Slovakia, measured as gross regional outflow as a percentage of working age population, is significantly lower than in most EU countries and other advanced economies as well as neighboring Visegrad countries (see for example Paci et al, 2007). According to national statistics, 1.6% of the productive age population (15-64y) changed their place of residence in 2011, of which 46% moved between municipalities within districts (i.e. short distance migration), 29% between districts within a region and 25% between regions. These figures are remarkably stable over time (there are only minor variations in data between 2000 and 2013), implying that the overall internal migration capacity and main flows are relatively unresponsive to external factors such as international migration or policy interventions. No more than 3 to 4 percent of residential migrants (3.3% in 2011) indicate employment-related motives as the reason for relocation. "Housing reasons" and "following a family member" account for almost two thirds of officially declared migration reasons. The share of labor migration increases with the spatial distance of relocation and is the highest in migrations between regions (8.5% of all inter-regional migrations in 2011; in comparison, employment reasons were stated in merely 1.1% of relocations between municipalities). Jurcova (2011) points out that this observation is consistent with data on the educational structure of migrants and the general assumption that propensity to move for work increases along with educational attainment.

When processing graphs and tables we used data from the national statistics - Ministry of Transport, Construction and Regional Development of Slovak Republic, Centre of the Institute of Informatics and Statistics (INFOSTAT), Statistical office of Slovak Republic, Eurostat data, research reports and OECD studies.

Discussion

In recent years, Slovakia has taken a number of measures to address housing issues. Law on the State Housing Development Fund entered in force since 2014 and supports public and private rental housing. The law on short-term leases entered into force in May 2014 and it promotes flexibility in the housing market and the growth of rental housing sector by establishing a specific legal regime for private-sector rental housing. Since last year, in the social housing sectors entered into force new restrictions concerning the level of subsidies. However, statistics show a declining number and proportion of municipal rental housing. One of the determinants that influence the decision between rental or buying (i.e. owner-occupied) is the criterion price (annual rent). Quantitative assessment of the advantages of ownership or lease of the property consists of comparing the average house prices to average annual price of renting a comparable property(Car, 2014):

$$\textit{The ratio of rental price} = \textit{price of residential property} / \textit{average monthly rent} \times 12 \quad (1)$$

The simplified ratio shows that how long does it take (normally years) from the value of lease to accumulate the amount that would allow to ensure average housing. In this context, in Slovakia, custom monthly rental price of intensive is often compared to the amount of monthly payment of possible housing loan. In the case of relative equality of the monthly rent and monthly payment of the loan, there is a high probability that the household chooses to purchase their own housing. In connection with the evaluation of the property under criteria of price / annual rent, there are some general empirical boundaries to determine their degree of objective evaluation. By this way, it is possible to reach an attitude that the property can be regarded as fair if the ratio of prices and rents represents a value of 14.2 years. This value corresponds to the reciprocal value of 7 percent of the gross revenue from the residential property rent. If the price of owner-occupied housing is too high, potential customer will logically prefer to live in rented accommodation (Car, 2014). This usually reduces the demand for new construction and brings the price of owner-occupied housing closer to

the price of rent. When the ratio of owner-occupied housing and rental housing prices remains high for a long time, it means that housing prices are set on unrealistic expectations of their future significant recovery compared with the reasonable rent and therefore the price of housing is likely to be overstated. In case of criteria price / annual rent, it is appropriate to compare not only its level, but also the dynamics, which also shapes the evolution of housing prices.

Criterion of price / annual rent can be included in a very important indicator in assessing the stability but also a possible overheating of the housing market. At first glance, it seems illogical that the person interested in purchase of a house or apartment would also address the situation in the rental market. However, there are several reasons why potential housing market participants should pay attention also to other evaluation parameters. Value of criteria price / annual rent below 12.5 indicates undercut house prices and encourage the purchase of real estate - is more profitable to buy than pay rent. In such situations, it is advantageous to buy property also with a view to its subsequent rental. On the other hand, value of criteria price / annual rent is higher than 20, it means overestimation of house prices and the cost of purchasing real estate is higher than the costs associated with its rental. In such a situation, any purchase of real estate is disadvantageous. Range of relatively reasonable prices of residential properties in accordance with the criteria of price / annual rental values between 12.5 to 20 corresponds to the reciprocal range according to the criteria of gross rental income between values from 8% to 5%. Values of criteria from this range indicate that the prices of the houses and apartments are at reasonable values. Residential property prices are becoming much understated if the value of the criterion price / rent is less than 6.7 and gross rental yield is over 15%. On the other side, house prices are becoming much overvalued if the value of the criterion price / rent is higher than 40 and gross rental yield is below 2.5% (see Table 1).

Table 1 : Scoreboard for real estates in the housing market

The ratio of price / rent	Gross rental yield (%)	General evaluation
6.7	15	Very undervalued
10.0	10	Undervalued
12.5	8	On the edge of underevaluation
14.2	7	Fairly valued
20.5	5	On the edge of overvaluation
33.3	3	Overvalued
40.0	2.5	Very overvalued

Source: Global Property Guide, 2015

An important prerequisite for a reliable assessment of whether house prices are overvalued or undervalued is availability of relevant data about property prices and rentals.

Conclusion

Focus on promoting owner-occupied housing with existing instruments creates some distortion in the housing market. There are options that will help to correct the current status and to avoid possible future complications. One of them is redirecting state support on owner-occupied housing to financial contributions on housing (housing allowance). This tool of housing policy would allow the recipient to choose between rent and owner-occupied housing. This means that financial contributions could be more bonded on income and other social criteria and thus achieve greater reinvigorating of the resources. Strengthening of this tool in Slovakia is recommended also by OECD (2009). Based on the experience of many developed countries (e.g. Great Britain), another solution for improving mobility in Slovakia, in particular the labor mobility of tenants of social rental housing could be the creation of databases of rental housing and the subsequent connection to a database of jobs. Creation of such a service would allow job seekers to find the available rental housing and job at the same time.

Electronic Government Portals and its Impact in the Successful Application of E-Tenddering Systems

Dr. Sahem A Nawafleh

Department of e-business & Commerce

University of Petra-Jordan

Email: Snawafleh@uop.edu.jo

Sahem_nawafleh@yahoo.com

Abstract:

This study aims to examining and analysing the role of Electronic government in the world through the mechanism of selecting and implementing of public and private institutions for the E-tenddering system conducted with each other. The successful implementation of Electronic government programmes highlightes important issues at the global level in the success of organizations in the implementation of E-tenddering system successfully. Also this study discussed the role of the Electronic government programme in Jordan through the application of E-tenddering system in public institutions within the country. The subject has been discussed through a field study designed to identify and interview some general organization that works on the same subject; study found a set of conclusions and recommendations about the topic.

Procedural Definitions: Electronic government, e-gate, E-tenddering system

1. Introduction:

Cullen A., Elsheikh Y, and Hobbs D., 2007, Icts revelotin is affecting all our life aspects. One of the significant effects of this revolution is promoting change in the way the Government dealing with its ministries, governmental departments, businesses sectors and other partners such as citizens in General, and governmental officials through the services provided by them. The term Electronic government emerged as a result of the informatics revolution and information technology in order to improve the services provided and the shift from traditional to electronic delivery of services within the community. One of the significant objectives Electronic government seeking to improve order and regulate the relationship between the public and private sector in terms of organizing tenders and E-tenddering system.

E-tenddering system is considered the most important mean employed by departments for developing public utilities; therefore, such contracts must include some conditions and concessions that will help public sector institutions.in this study, researchers will try in this field study to highlight and indicate the most important standards and procedures brought about by the Electronic government programmes for the successful implementation of E-tenddering system in terms of applicationin addition, to identify the main causes that lead to non-compliance with conditions and procedures for a successeful implementation of E-tenddering system.

2. Litreture review:

- ✓ **E-Government**: Sahem Nawafleh, et al, 2012, Is the use of new technology to improve the government methods of service delivery, or it is changing services performance from a routine, bureaucracy, multiplicity and complexity of procedures method to a method depend on the use of new technology to improve the services performed by the government targeting to deliver it for the citizens in a simple way through using internet.

The term e-Government is achieved through some basic conditions, such as accountability and flexibility. Of the positive factors of e-Government is working to reduce possible illegal and suspicious relations for officials and employees

- ✓ **E-Government objectives:**

The following the most important e-government objectives according to Matthias Finger and Gaëlle Pécoud, 2003:

1. Increase the efficiency and effectiveness of the procedures and processes within the Government through the use of information technology in reducing the time in performing the work with accuracy in completing this work.
2. Reduce Government expenses and costs through improving and developing of business processes with high transparency
3. Increase the users' satisfaction of the electronic services provided by the Government to reduce the time required to perform those services.
4. Increase integration between Government and private enterprise in serving countries in general.

- ✓ **E-Government partners:**

Jordan E-Government Program 2006, It aims to provide users with governmental electronic services through the government sites on the internet to deliver their personal needs such as access to public or private documents, as documents of general nature does not requesting verification of the client such as registration certificate in the commercial records.

Bernd W. Wirtz Peter Daiser, 2015, E-Government plays the role of regulator, tax collector and customer support for businesses regardless of the service or product provided by private sector organizations, of the essential services the Government provides under its relation with the business organization is tax e-performance.

Andersen, K., 2006, E-Government aims coordinate between governmental devices to perform businesses in an integrated manner at all administrative levels, as well as the relationship between central organizations and local devices such as exchanging data, information about regulations, rules, work systems and procedures in business performance. The local organizations are linked through internet and achieving integration in services that involve more than one governmental sector.

In order to improve staff performance and clarify the methods through businesses are performed; information technology is used in human resources management which includes self-services provided to staff like obtaining leave and accessing to e-training and efficiency reports.

- ✓ **E-Tendering:** David Chaffey (2012), Organizations of all sizes are interested in E-Tendering in order to reduce the costs incurred by those organizations generally for procurement. That's why these organizations moved to procurement strategies through the bidding system to get rid of purchasing high costs and thus increase the efficiency of the organization.

Public and private organizations significantly concerned in improving procurement and it practices intense scrutiny on the procurement process which has led to the cancelling many projects and therefore employees' dissatisfaction and some whimper from stakeholders.
Traditional tendering system was implemented on traditional methods, used paper and emails to send and receive requests, so that the traditional method generally lead to wasting time, effort and resources, therefore taking inaccurate decisions as a result of inaccuracy of the available data, which generally reflected negatively on bids because of the limited tender participants and finally failed to execute those bidding successfully and thus increase costs and significantly wasting employees efforts. As a result of all of these reasons, public and private organizations have resorted to E-tendering.

E-tendering is a collection of interconnected electronic processes aimed at managing the tender from advertising stage till final stage. That is it's a central process that helps organizations to overcome the high costs associated with traditional tendering costs through electronically advertising and increasing procurement integration, as well as to increase society acceptance of electronic transactions within E-tendering .

In addition, E-tendering aims to achieve transparency and effective internal audit through E-tendering system in procurement throughout the world, resulting in increased dealing with those electronic systems and widely accepting them. In addition E-tendering systems provide instruments and mechanisms for the advancement of electronic bidding and arranging access to documents and forms for participating in E-tendering system, and the needed tools to resolve disputes that may arise between buyers and sellers.

✓ **E-government Portals**: E. Turban, et al, 2008, Portals have become an integral part of basic infrastructure project for any e-Government; it represents the frame including all components and other systems necessary for the citizen and the Government alike. Pushing most Governments interested in e-Government to build a port or an integrated Government Portal supported by several applications that integrate and unite in interface form concerned with citizen and focus on investor; so through they are able to get all government services they need, thus achieving a citizen satisfaction about the service and fulfilling and fitting its requirements.

3. Discussion of the study:

The study aims to examine and analyse the role of Electronic government programs for effective, successful commitment and execution of tenders and contracts conducted between the public and private sector institutions in terms of all procedures and norms to participate and engage in government tenders; the need for such procedures and standards are clear and available to everyone through the e-portals of the ministries and governmental departments and are applied with high transparency. From this perspective the study seeks through this part to identify the field side of research and statistical procedures and methods that were used, data analysis and study questions, as well as the study sample, it also demonstrates the statistical analysis, data analysis and variables that are illustrated by tables, and developing a set of recommendations in the same area through the survey results.

✓ **Study questions**:

- Are the required standard conditions in the tender and E-tenddering system through Electronic government portals available?
- How are these standards applied in Jordanian ministries and institutions (Electronic government)?
- What are the main actions and procedures Jordanian institutions (Electronic government) follows in organizing tenders and bids and contracts? Are they available on the Electronic government portals?
- What are the organizational factors within institutions (eGovernment portals) that affect the successful implementation of tendering and E-tenddering system?

✓ **Statistical methods:**

A group of methods were used like statistical Analysis package "SPSS", the Arithmetic Median, Repetition, Percentages and Standard deviation in order to examine the relations between the study areas by relying on analysis of variance "OWN WAY ANOVA" to determine significant statistical differences for demographic variables and using F test and Level of Significance to examine the basic hypotheses.

Table (1) representative sample characteristics:

Sex	***frequencies***	***percentage***
Male	139	67.9
Female	61	32.1

Total	200	100.0
Age	***frequencies***	***percentage***
18-25	19	5.0

46 – 55	37	17.0

More than 56	9	2.5
Total	200	100.0

Table "3" shows the participants' responses according to their gender:

Age group 18-25 years; the number of respondents were 19 members by 5.0% which is low in comparison with other groups, this is due to lack of experience and qualifications. Where the age group 26-35; the number of respondents were 75 persons by 40.9%, which is the highest proportion in the sample.

36-45 years: the number of respondents was 60 individuals by 34.6% and is close to the previous category. Through studying the previous two groups; they were staff of administrative, professional and various engineering posts.

Age group 46–55 years: the number of respondents was 37 by 17.0%; which includes department heads and managers. While, age over 56: number of respondents were 9 by 2.5%, which is the lowest and indication they of being within retirement age.

Table 4

Current job	***Number***	***Percentage***
Director	15	5.7
Head of Department	35	15.8
Engineer	61	32.0
Head of Division	21	6.9
Other	68	39.6
Total	200	100.0

Table "4" shows the sample responses according to their current job, and is divided into five categories; where the incumbents of the position of other functions are the highest where number of the respondents was 68 employees by 39.6%. Followed by the engineer's category where the number of respondents was 61 engineers by 32.0%; being the category that oversees the effective implementation and standard conditions of execution. Then the of department heads where number of the respondents was 35 individuals by 15.8%, after that the head of Division where number of the respondents was 21 by 6.9%, and finally the directors where number of the respondents was 15 and 5.7%, this shows that any department where senior management levels are the lowest due to lack of experience and qualifications.

Table 5

Years of experience	***Number***	***Percentage***
1-5 years	23	10.0
6-10 years	33	17.6
11-15 years	62	32.8
16-20 years	52	26.4
More than 21 years	30	13.2
Total	200	100.0

Table "5" shows the sample responses according to their Years of experience, which indicates that the highest percentage among respondents is the third category (11-15 years) where the number of respondents was 62 employees by 32.8%, followed by (16-20 years) where the number of respondents was 52 employees by 26.4%, and then (1-5 years) where the number of respondents was 23 by 10.0%; this indicates that respondents who responded to the survey are those of long and high experienced.

Table 6

Educational level	*Number*	*Percentage*
Less prescriptive	12	4.4
Guideline	25	10.7
Diploma	57	29.5
BA	89	49.7
Postgraduate studies	17	5.7
Total	200	100.0

Table "6" shows the sample responses according to their Educational level, where the number of staff who do not hold a steering certificate are 12 employees by 4.4%, while the number of staff who hold certification guideline was 25 employees by 10.7 and the number of diploma holders are 57 employees by 29.5%; and the number of Bachelors holders was 89 employees by 49.7% which is the highest percentage, indicating that individuals who responded to the study questions are holdersof diploma, undergraduate and graduate degrees. While the number of advanced degrees holders was 17 employees by 5.7 %. This indicates the management consideration of recruiting staff with certifications and experience.

- ✓ **Analysis by area of study:**

First field: Electronic government portals provide standard requirements in the tender and E-tenddering system.

Table 7 Arithmetic averages, standard deviations and the ranks of the first area descending

Class	*REF.*	*Paragraphs*	*Arithmetic mean*	*Standard deviation*
1	9	Electronic government portals provide clear and specific standards for the tenddeing systems.	1.99	0.75
2	8	standards measure the activity related to performing work effectively	2.44	0.94
3	1	There is acceptance and satisfaction of applicable standards	2.87	1.00
4	6	Standards are within the objectives and conditions of the tender	2.52	0.96
5	3	standards are accessedand achieved easily on the portals	2.61	0.97
6	4	The standards aim to access the strengths and weaknesses of tendering.	2.66	0.96
7	2	Protecting public interest with regard to the implementation through work phases	2.47	1.02
8	7	Effectiveness measurement system affects the objectives of the contract parties and beneficiaries	2.50	0.82
9	5	Research on how to improve and raise the effectiveness of performance	2.49	1.04

Table "7" shows the sample responses about Electronic government portals provide standard requirements in the tender and E-tenddering system; the table reveals that the third paragraph obtained the highest rank with Arithmetic mean of 2.87 and standard deviation of 1.0, followed by sixth paragraph

with Arithmetic mean of 2.66 and standard deviation of 0.96; This indicates that the standards and crateria aims to reach to the strengths and weaknesses of tendering. Followed by the fifth paragraph with Arithmetic mean of 2.61 and a standard deviation of 97% and this underlines the flexibility, accessibility and achievement of these standards.while the paragraph came fourth in with Arithmetic mean of 2.52 and a standard deviation of 96%. Which seventh one with Arithmetic mean of 2.47 and standard deviation 1.02 emphasize to protecting public interest with regard to the implementation through work phases'.

Table 8 Procedures for participation in the tender through Electronic government portals:

Class	***REF.***	***Paragraphs***	***Arithmetic mean***	***Standard deviation***
1	12	Actions are donating simplicity and clarity	2.91	0.90
2	14	procedures are developed and updated constantly on the Web portal	2.87	0.94
3	15	The procedures contribute to protect e-tendering Parties	2.77	0.90
4	11	The procedures apply to all kinds of E-tenddering system	2.68	0.91
5	13	The Portal provides access to the procedures at any time by the e-tendering parties.	2.61	0.97
6	10	Procedures are Compatible with emerging circumstances and variables during execution	2.56	0.19

Table "8" shows the sample responses about the procedures for participation in the tender through Electronic government portals; where the paragraphs concerning procedures got the highest Arithmetical mean for respondents estimates, as the paragraphs (12, 14, 15) achieved the highest Arithmetical mean respectively (2.91, 2.81, 2.77) ; this indicates that the procedures followed on the tenddring systems' implementation dominated by simplicity and clarity and are flexible as it is simply updated, modified and contributed to the protection of the tender parties without affecting the succesful and quality of implementation.

Where the paragraphs (10, 11, and 13) got moderate Arithmetical mean ranged between (2.56-2.68) which emphasizes the considering of procedures to the conditions, variables, the accessibility to these procedures and the application of these procedures to all types of E-tenddering system.

Table 9 Electronic government portals keep pace with technology and technology

Class	***REF.***	***Paragraphs***	***Arithmetic mean***	***Standard deviation***
1	21	There is a concern about studies and research related of e-tendering systems.	3.01	11.08
2	18	Tools are periodically developed and updated contunously.	2.97	0.94
3	17	Availablility of necessary hardware and software for e-tendering system	2.89	0.79
4	16	E-tenddering system process are implemented with high-tech methods and tools	2.79	0.97
5	19	Efficient communication between the e-tendering parties	2.68	0.95
6	20	Ability to access to e-tendering information at any time	2.66	0.97

Table "9" shows the sample responses about Electronic government portals keep pace with technology and technology, which indicates the management concern in research and scientific studies and trying to apply it fully as paragraph 21 obtained the highest Arithmetic mean of 3.01, followed by paragraph 18 with Arithmetic mean of 2.97 which indicates that the methods used in the implementation are development and updated constantly, Then followed by paragraph 17 with Arithmetic mean of 2.89; to confirm that the management possesses technologies and methods used in measuring the implementation effectiveness. While, Paragraphs (16, 19, 20) respectively, with Arithmetic mean of (2.79, 2.68, 2.66) emphasize the ability of efficient communication between the tender parties during implementation as well as Ability to access information at any time by the tender parties.

Table 10 Arithmetic means and standard deviations for independent variables

REF.	Area	Arithmetic mean	Standard deviation	Reliability coefficient
1.	standards	2.451	0.9457	0.8891
2.	Procedures	2.675	0.9448	0.7848
3.	Tools and technology	2.745	0.9921	0.8819
4.	culture	2.154	0.9923	0.7928

Table "10" shows the sample responses about Arithmetic means and standard deviations for independent variables; after analysing the 4 paragraphs, it was found that the standard conditions ranged between 0.9457- 0.9923for all paragraphs and questions. i.e the first paragraph about the existing standards obtained Arithmetic means of 2.45 and a standard deviation of 0.9457 and stability coefficient of 0.8891; which is a worthy percantage donating that Electronic government portals adopt standard conditions and specifications for global influence, contribute to measuring the success of implementation of these tenders and E-tenderring system and emphasizes access and application of those standards. This emphasized that Electronic government Portal provides standards, conditions and specifications that should be adhered to when implementing tendering systems and projects, such as criteria and conditiones for applying and participating in Government tender,technical standards, financial terms and conditions.

analysis the questions of the second paragraphs about administrative procedures contributing to and influence the effectiveness application of E-tenddering system; it has obtained Arithmetic means of 2.67, standard deviation of 0.9448 and coefficient of 0.7848 which is not decent indicater of adherence and compliance to those procedures in the E-tenddering system effectively..

Given the above results, it is noted that they reflect very high ratios and also emphasizes that the eGovernment Portal provides standard conditions used in E-tenddering system and the access to those standards.

4. Discuss the Study Questions

Comparison between established study questions and statistical analysis of questionnaires and personal interviews; a substantial similarity and lack of variances in results were concluded:

- ✓ Are there standard conditions required in the tenders and E-tenddering system through Electronic government portals?

Through the participants answers to this question in the first paragraph of the questionnaire; it is concluded that Electronic government Portal includes conditions and criteria must be available in the E-tenddering system when implementing, and this has been confirmed through respondent’s answers. These answers were Convergent, and have no significant differences, which stress that, the criteria and conditions for the implementation of the E-tenddering system.

- ✓ To what limit these administrative standards applied in the e-tenddernig systems in the Jordanian Electronic government portals?

The results of the personal interviews for the sample participants regarding this question disclosed a significant application for these conditions and standards in Jordan since it is not possible for any particpant to participate in the tenders if not providing acertain bail in application to the financial terms issued on the Electronic government Portal, and offers experience certificates that indicates and prove that he has a high experience in order to ensure proper application.

- ✓ What are the main actions and procedures which the Jordanian institutions (Electronic government) follow in organizing tenders, bids and whether they are available on the Electronic government portals?

Through answer the the second paragraphs questions the sample participants there are some proceduers:

- The announcement of a "tender" in daily newspapers for three days and provide those ads on Electronic government Portal.
- Registration and applying tender through the Ministry web portal.
- Scheduling contract applications during a certain time period (online).

- ✓ What are the organizational factors within institutions (eGovernment portals) that affect the successful implementation of tendering and E-tenddering system?

As the results showed that these factors affect positively or negatively on the success implementation of the tendering.

5. The results of the study:

The results of the study showed, especially by answering questions that:

1. Electronic government Portal offers certain standards and criteria clarify the conditions of implementation which must be identical and with high degree of effectiveness.
2. The implementation of the tendring system starts from the moment of the announcement of the contract to the stage of performing contract terms that advertised through the web portal.
3. Electronic government Portal provides a comprehensive view of the procedures and deterrent sanctions when violating regularities and non-compliance with the terms and application procedures of the tender by the parties, and the effects in terms of rights and duties.
4. demographic variables "sex, age and type of activity and the years of experience and educational level"; revealed that there are no statistically significant differences in the responses of individuals where all are converged signifying that Electronic government Portal provides clear standards and specifications necessary for the contract implementation of and commitment to the contract procedures and implementation.
5. The necessity to provide all the techniques and modern technology in the field of E-tenddering system and bids and the importance of its availability on the portal to enableall parties with transparency of access.

An Application on Web Path Personalization

Nicoleta Enache-David, Transilvania University, Brasov, Romania, nicoleta.enache@unitbv.ro
Livia Sangeorzan, Transilvania University, Brasov, Romania, livia.sangeorzan@gmail.com

Abstract

The models based on the Markov property are well known for modeling the users' navigational behavior in a web site. In this paper we propose an algorithm that computes the preferential navigational path. The model can be used for web path personalization on a website in order to meet the characteristics and preferences of the users.

Keywords: web path, navigational path, page rank.

1.Introduction

Markov models have been widely used for modeling the users' navigational behavior in a web site. The models based on the Markov property are based on the transition probabilities between web pages, as recorded in web log files. In their paper, the authors Khashman and Nwulu (2011) mentioned that neural networks can be also used as prediction models.

Web usage mining represents the set of techniques used for the study of the users' behavior during navigation on the Internet. A common problem modeled by the Markov chains is computing the navigational paths used by the users during their navigation on a web site as Eirinaki et al (2005) and Sangeorzan (2008) mentioned. Though, Markov models do not handle the case when a path is not included in the training data or is included in low frequency and cannot provide good estimates of the corresponding transition probabilities. The authors Eirinaki et al (2005) used the approach that a page or navigation path is important if many users have visited it before and the prior probabilities are assigned to the pages using a Page Rank type algorithm. In this paper we propose an algorithm that computes the preferential navigational path on a web site during a period of time and can be used for the optimization of the structure of the website. This way, one can predict the preferences of users, if one knows the pages visited before in the preferential navigational path as one can see in papers of Enache David et al (2013) and Sangeorzan et al (2013). Our future work will be focused on adapting the model to complex informatic systems, like the ones described in the papers of authors Carstea (2013), Carstea (2015) and Sangeorzan (2008).

2.Preliminaires of PageRank

In web mining literature there exist a lot of research papers based on a stochastic modelling of the users' navigational behaviour in a web site, as one can see in research work of Srikant (2011) and David and Sangeorzan (2009).

Let us consider a web site modelled as a directed graph $G=(S, X)$, where S is the set of nodes and X is the set of edges. In this model the nodes represent the web pages and the edges represent the links between them as is mentioned by David (2011). The random walk on G induces a Markov chain, where the states are given by the nodes in G and the stochastic transition matrix is denoted by P like in formula (1). The probabilities p_{ij} describe the one-step transition from page i to page j and $p_{ij}=0$ if there is no link between page i to page j.

$$P=\{p_{ij}\}_{i,\,j=\overline{1,n}} \quad \text{and} \quad \sum_{i=1}^{n} p_{ij}=1,\ j=\overline{1,n} \qquad (1)$$

The PageRank algorithm is the most popular link analysis algorithm, used broadly for assigning numerical weightings to web documents. Web search engines use this algorithm in order to rank the retrieved results.

The algorithm models the behavior of a random surfer, who either chooses an outgoing link from the page he is currently at, or he goes to a random page after a few clicks. The PageRank of a page is defined as the probability of the random surfer being at some particular time step $k > K, K \in N^*$ at this page. The authors Eirinaki et al (2005) mentioned that the probability is correlated with the *importance* of this page, as it is defined based on the number of the pages pointing to it.

3. Preferential Path algorithm

We assume that the log files have been preprocessed and contain distinct user sessions. Next we will give the definition of a user session.

Definition 1: A user session denoted by US is defined as a sequence of states $X_k \in S, k \in \{1,...,n\}$.

3. 1. Transition Probabilities

We denote by w_{ij} the number of times the page X_j was visited right after page X_i. It means that w_{ij} is computed as the sum of the weights of all directed edges between nodes X_i and X_j. In Eirinaki et al (2005) the authors define w_i as the sum of all the weights of edges pointing to $X_i, i = \overline{1,n}$:

$$w_i = \sum_{k \in In(X_i)} w_{ki} \quad (2)$$

Using these weights, we can estimate the prior probabilities of the web pages and the transition probabilities between two pages.

Definition 2**:** The probability of a transition between two pages X_i and X_j is defined like the following:

$$P_{ij} = \frac{w_{ij}}{\sum_{k=1}^{n} w_{ik}}, \; i, \; j = \overline{1,n}. \quad (3)$$

We consider the transition matrix denoted by P:

$$P = \{p_{ij}\}_{i, j=\overline{1,n}}. \quad (4)$$

3.2. Prior Probabilities

Eirinaki et al (2005) mentioned that there exist many approaches for assigning initial probabilities, i.e. prior probabilities, to the states of a Markov model. One of them assigns equal probabilities to all states. Another approach estimates the initial probability of a page as the ratio of the number of times this page has been visited as a first page to the total number of user sessions. The researches have proven that neither of these approaches provides accurate results in the case of modelling web navigational behaviour.

The initial probability of a page should reflect the *importance* of a page in the web navigation. Eirinaki et al (2005) compute the pages probabilities taking into account a variant of the Page Rank algorithm.

We propose the PreferentialPath (PP) algorithm that computes the preferential path using the edge weights. It can be used for websites structure optimization, by creating additional links between the start state and the states from the preferential path. In figure 1 the PP algorithm is presented.

The PP algorithm starts with the state X_1 and computes the maximum weights of the outlinks. The output is the preferential path that consists of the pages that are directly linked each other and have the maximum weights.

Input Data

- Website's pages $X_1,...,X_n$
- $W=\{w_{ij}\}_{i,j=\overline{1,n}}$ set of edge weights (number of times X_j was visited right after X_i)
- $P=\{P_{ij}\}_{i,j=1,n}$ where $P_{ij}=\frac{w_{ij}}{\sum_{k=1}^{n} w_{ik}}$, $i,j=\overline{1,n}$.

Algorithm PP (Preferential Path)

```
i=1 {X1 is the start page}
M={X1}
repeat
  max=-1
 for j=1,n
   if ( P_ij ≠ 0 and max < P_ij ) then
     max= P_ij
   end if
  repeat
  Add X_j to M
   i=j
until X_j =F
```

Output Data

$$M=\{X_1, X_2,..., X_j, F\}$$

Fig. 1: The PP algorithm

4. Experimental Results

We consider a website having 9 pages: $X_1, X_2,..., X_8, F$, where X_1 is the start page and F is the log off page. The user sessions have been collected from the log files for a period of time. The user sessions are presented in Table 1.

Table 1: User sessions

User Session No.	Path
1	$X_1 \rightarrow X_2 \rightarrow X_1 \rightarrow F$
2	$X_1 \rightarrow X_2 \rightarrow F$
3	$X_1 \rightarrow X_2 \rightarrow X_8 \rightarrow F$
4	$X_1 \rightarrow X_2 \rightarrow X_5 \rightarrow F$
5	$X_1 \rightarrow X_3 \rightarrow X_1 \rightarrow F$
6	$X_1 \rightarrow X_3 \rightarrow X_5 \rightarrow X_3 \rightarrow F$
7	$X_1 \rightarrow X_3 \rightarrow X_6 \rightarrow X_3 \rightarrow F$
8	$X_1 \rightarrow X_4 \rightarrow X_6 \rightarrow F$
9	$X_1 \rightarrow X_4 \rightarrow F$

In Figure 2 we represent the navigational graph that illustrates the users' navigation sessions.

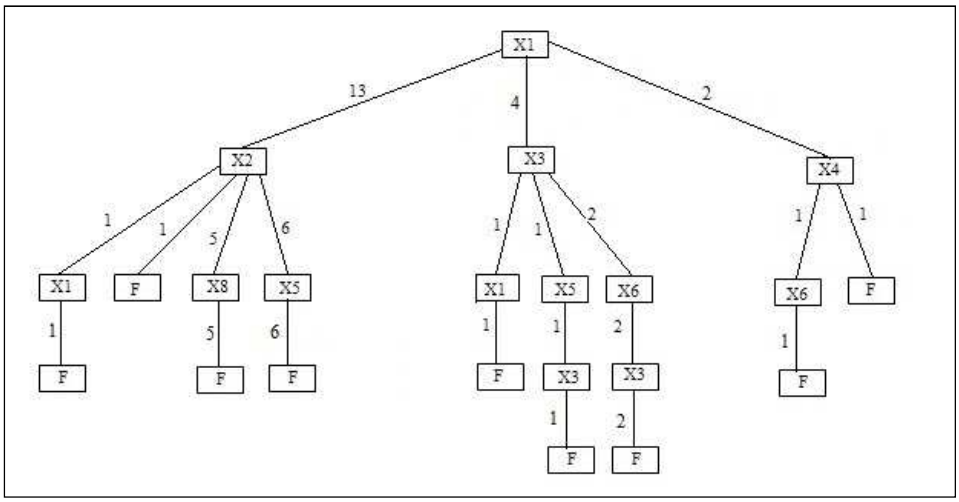

Fig.2: Navigational graph

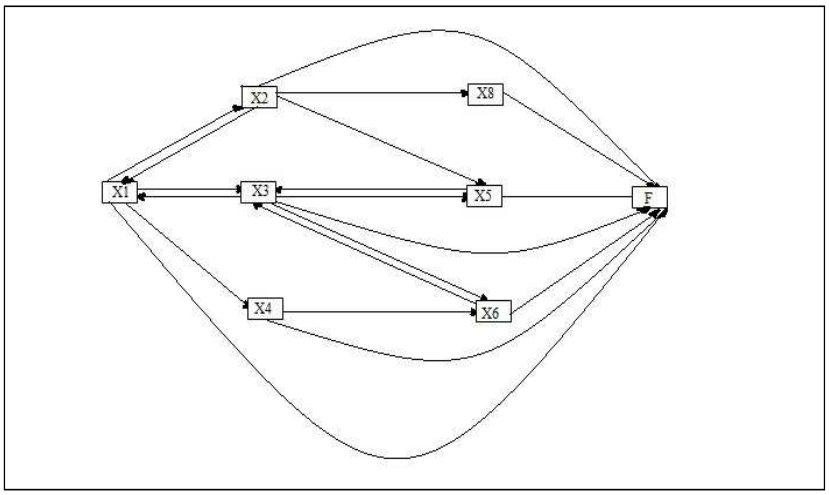
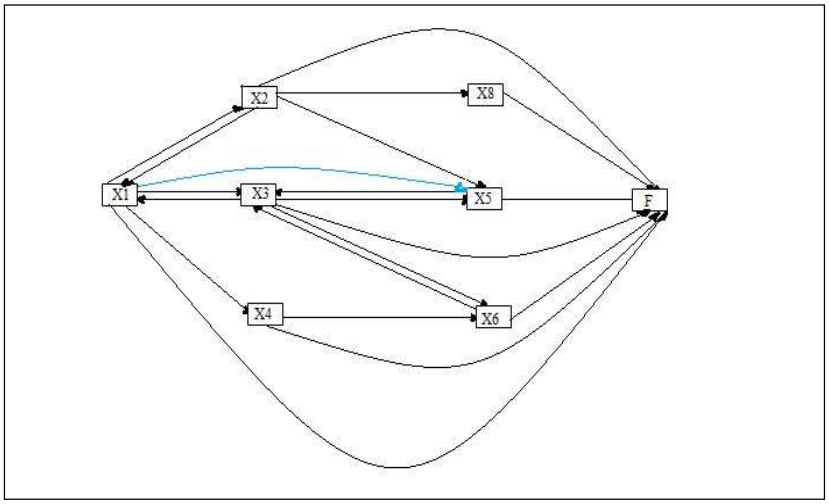
Applying the PP algorithm, we obtain the preferential path $M = \{X_1, X_2, X_5, F\}$. We can add an additional link between the states X_1 and X_5, like in figure 3. It means that the users that are interested in navigating on the preferential path $\{X_1, X_2, X_5, F\}$ can go directly from the start page to page X_5, where they find useful information.



a) initial structure



a) adding a new link

Fig.3: Markov chain synopsis

5. Conclusion

In this paper we propose an algorithm that computes the preferential path on a web site. Our approach is based on a Markov model that assigns weights for all the edges using the number of visits recorded for every edge during a period of time. The algorithm can be used for the optimization of the structure of a website by adding additional links between the start page and the pages from the preferential path. This way the users can have a direct link from the start page to a certain page they are interested in. The model can be extended to meet the characteristics and preferences of the users.

This model can be used in marketing purposes, by placing advertisements, banners or product offers on the pages from the preferential navigation path.

Abstract

Cet article vise à analyser le rôle du capital immatériel d'une coopérative et d'une entreprise familiale du secteur agroalimentaire dans le processus de création de valeur. L'attachement au territoire constitue un point commun entre ces deux entreprises et explique leur positionnement stratégique. Cet article défend l'idée que l'ancrage territorial de l'entreprise combiné avec les différentes composantes du capital immatériel identifiées (capital humain, organisationnel et relationnel) constituent pour ces PME un atout stratégique majeur sur leurs marchés et contribuent de manière importante à la création de valeur. Cette recherche est exploratoire et à visée compréhensive.

Mots clés : Capital immatériel –PME - Terroir – Etude de cas

Introduction

Depuis le début des années 90, les travaux de recherche portant sur l'importance de la dématérialisation économique se sont multipliés (OCDE, 2013). Les TPE/PME agroalimentaires investissent de plus en plus dans l'immatériel (image de marque ou capital humain par exemple), mais les richesses accumulées sous forme d'actifs immatériels ne sont pas visibles dans les états financiers (Thésaurus-Bercy V1, 2011 ; Louzzani, 2016). Un autre phénomène prend de l'ampleur dans ce secteur agroalimentaire en France, celui de la célébration de l'authenticité ; le retour aux produits alimentaires de terroir.

La littérature n'aborde que très peu les modalités de création de valeur à travers les actions des dirigeants de PME de terroir en matière de la mobilisation et du développement du capital immatériel (Louzzani, 2013).

Cet article défend l'idée que l'ancrage territorial de l'entreprise combiné avec les différentes composantes du capital immatériel identifiées (capital humain, organisationnel et relationnel) constituent pour ces PME un atout stratégique majeur sur leurs marchés et qui contribue à la création de valeur. Cette recherche est exploratoire et à visée compréhensive (Yin, 1994).

Dans la première partie de l'article, nous précisons la notion de terroir et celle du capital immatériel en lien avec le mode de création de valeur. La deuxième partie est consacrée à la présentation de la méthodologie et à la description des deux PME de terroir. La dernière partie est consacrée à l'analyse et à la discussion du rôle des trois composantes du capital immatériel (humain, organisationnel, relationnel) en lien avec l'ancrage territorial des PME et leur mode de création de valeur.

1. Le Capital Immateriel Et La Notion De Terroir Au Cœur Des Modes De Creation De Valeur

1.1. Les différentes facettes de la notion de terroir et ses implications managériales

L'agroalimentaire possède un dispositif réglementaire qui permet aux entreprises de bénéficier des attributs institutionnels (tels que l'AOP, appellation d'origine protégée, l'IGP, indication géographique protégée, AB, Agriculture Biologique, …). Ces attributs que l'on qualifie de labels sont reconnus comme de terroir et permettent de communiquer sur l'origine et/ou la qualité des produits.

Ils permettent d'établir une relation de confiance entre les consommateurs et les acteurs de la filière alimentaire (Pichon, 2006).

Le « refus de l'opacité du système alimentaire et la volonté de retrouver du lien entre le producteur et le consommateur, traduisant une forme d'attachement au territoire » constitue une des tendances observées dans l'acte d'achat du consommateur (Laisney, 2012). Avec Casabianca et al. (2005), on peut considérer le terroir comme « un espace géographique délimité, où une communauté humaine, a construit au cours de l'histoire un savoir collectif de production fondé sur un système d'interactions entre un milieu physique et biologique et un ensemble de facteurs humains. Les itinéraires sociotechniques ainsi mis en jeu révèlent une originalité, confèrent une typicité, et aboutissent à une réputation pour un bien originaire de cet espace géographique ».

Les produits alimentaires qui sont considérés de terroir peuvent bénéficier d'un label lorsqu'ils ont un lien tangible avec le terroir déclinant une identité géographique et répondant à un cahier des charges précis. Ils peuvent aussi bénéficier d'une image de terroir construite par le mode de production, tels que les produits fermiers ou biologiques, ou par un effort important en marketing. C'est le cas par exemple des fromages P'tit Basque qui en dépit de l'évocation claire d'une région n'est qu'une marque commerciale du secteur agroalimentaire appartenant au groupe Lactalis.

Tout comme les produits, les entreprises de terroir « sont encastrées dans un tissu de relations sociales qui confèrent une identité propre à la triade marché-produit-territoire, ce qui conduit à évoquer une forte idiosyncrasie, liée notamment à des ressources, et/ou à des compétences propres, soit au milieu, soit aux acteurs » (Marchesnay, 2001a). Cet auteur propose une grille d'analyse qui distingue deux logiques d'action dominantes chez les dirigeants des entreprises, entrepreneuriale et patrimoniale (Marchesnay, 2001b). Dans une logique patrimoniale les dirigeants visent d'abord la pérennisation de l'activité et l'indépendance en termes de capital social. Alors que ceux qui sont mus par des logiques entrepreneuriales cherchent d'abord à prendre des risques et à entreprendre.

Cet auteur souligne la double légitimité de l'entrepreneur, concurrentielle et territoriale. La première a trait à sa performance, i.e. utilisation efficiente des ressources, et efficacité dans la conduite des activités de l'entreprise, réalisant un niveau satisfaisant en termes d'effectivité. La seconde rappelle l'importance de son attachement au territoire (i.e. son enracinement) et l'intensité des liens avec les acteurs du territoire (i.e. son imprégnation territoriale). Cet auteur qualifie l'entrepreneur d'entreprenant lorsqu'il est fortement attaché au territoire (de manière affective mais aussi technico-économique), adopte des structures adhocratiques et est sensible au niveau d'effectivité au sein de l'entreprise. Pour ce type d'entrepreneur l'intégration territoriale participe au renforcement de la performance concurrentielle.

1.2. Le capital immatériel comme un véritable potentiel de création valeur

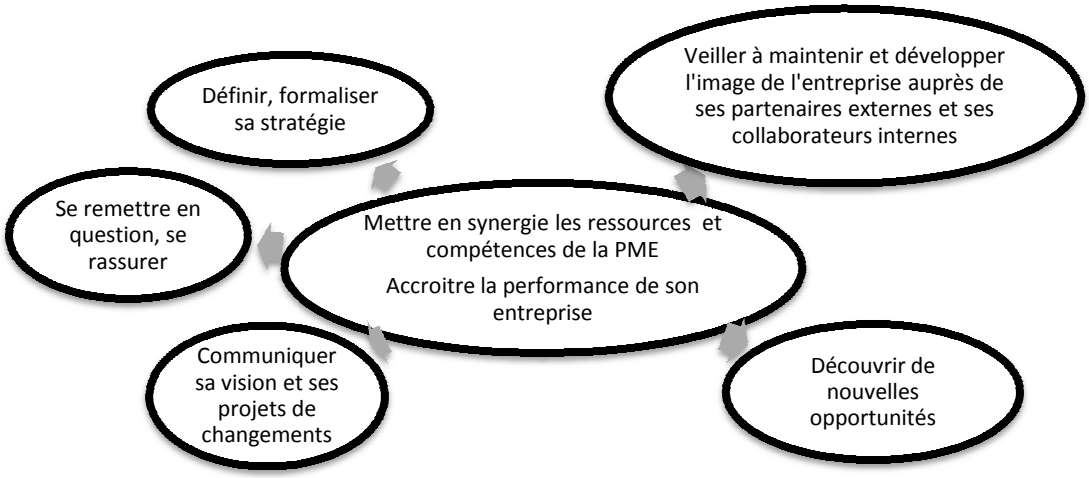
La notion de capital immatériel proposée par Leif Edvinsson dans les années 90 (Edvinsson et Malone, 1999) représente la valeur cachée de l'entreprise (Fustec, 2013). Dans une approche analytique on considère que les investissements immatériels dans la R&D, la formation, les activités commerciales, utilisés dans les détours de production, sont à mêmes de former le capital organisationnel, humain et relationnel des entreprises (Ngobo, 2013).

De nombreux auteurs considèrent que cette notion recouvre trois composantes essentielles incorporées dans les hommes et les organisations (Beattie et Thomson, 2010) :

- Le capital humain, qui représente le savoir et le savoir-faire individuel, les aptitudes et compétences des personnes et leur créativité pour développer des produits ou des services répondant à l'attente de la clientèle. On peut distinguer l'action qui conduit à la création de l'actif (ou le capital) et le capital lui-même (Thésaurus-Bercy V1, 2011). Un dirigeant qui crée un climat propice à la fidélisation de ses collaborateurs renforce le capital humain. Ce dernier enrichit la valeur patrimoniale de l'entreprise. Sa dépréciation se mesure par le turn-

over observé dans cette organisation. Ce capital est généralement scindé en deux types, capital dirigeants et capital collaborateurs. La valeur du volet dirigeants dépend du niveau de stabilité de l'équipe dirigeante, de sa compétence notamment en matière de vision stratégique claire et de sa capacité à prendre des décisions et des risques. Devant la difficulté de cerner le métier du dirigeant, le centre de ressources et de prospective propose un schéma synthétique qui met en évidence ce que pourrait apporter une formation aux dirigeants des PME (cf. schéma 1). Ce schéma permet de relier les activités du dirigeant, sa vision, son action, sa réflexion avec la performance de l'entreprise. Nous l'avons adapté pour mieux percevoir le rôle du dirigeant en tant que ressource intangible créatrice de valeur dans les PME. Le dirigeant vise donc par sa démarche entrepreneuriale à assurer le déploiement coordonné des actifs et ressources stratégiques et intangibles créant ainsi une compétence organisationnelle spécifique (Durand, 2013), créatrice d'un avantage concurrentiel et par conséquent de valeur. Dans notre analyse, la valeur d'une ressource se mesure par sa capacité à conjurer une menace ou à saisir une opportunité (Koenig, 1999) en gardant à l'esprit que les ressources tangibles ou intangibles, prises de façon isolée, créent rarement de la valeur (Grant, 1991).

Schéma 1 : Métier et activités managériales du dirigeant de la PME



Source : Adapté d'Observatoire des PME, 2005, p. 62.

Quant au volet collaborateurs, sa valeur se mesure par le niveau de compétence individuelle et collective, le niveau de fidélité et l'adhésion aux valeurs de l'entreprise.
En effet, les modes de gestion spécifiques, dans les PME, s'appuient sur des logiques de proximité (spatiale, hiérarchique, fonctionnelle, familiale) (Torrès, 2003).

- Le capital organisationnel qui représente ce qui permet aux flux d'informations et de décisions et au flux de matières de s'accomplir dans le cadre de la chaine de valeur interne de l'entreprise. Il est représenté par des bases de données, des processus de production, un système d'information, etc. En d'autres termes, tout ce qui permet l'amélioration de l'efficience organisationnelle.
- Le capital relationnel, exprime la capacité de l'entreprise à valoriser ses relations avec ses partenaires extérieurs clés.

Par conséquent, avec Lacroix et Zambon (2002) on peut considérer que le capital immatériel est un stock de ressources internes (compétence, savoir-faire, ...) et de ressources tournées vers l'extérieur (marques, réputation, ...) qui permet la combinaison et l'interaction de l'ensemble des ressources en vue de la création de valeur pour l'ensemble des parties prenantes par la recherche d'avantages concurrentiels.

Aussi nous défendons l'idée que pour les deux PME agroalimentaires ce qui permet à l'entreprise de se distinguer sur le marché des produits de terroirs du même groupe stratégique, au sens de Porter (1982), dépend de la capacité de la PME à mettre un dispositif managérial qui permet d'identifier et valoriser son capital immatériel (humain, organisationnel et relationnel) et l'adosser à l'ancrage territorial.

2. Méthodologie de l'étude et description des Deux PME

2.1. Méthode de collecte de données

L'étude empirique porte sur deux PME agroalimentaires de terroir, la COP[1] et la FAM qui sont deux entreprises fromagères auvergnates. Elle est exploratoire et à visée compréhensive (Yin 1994). Le travail de collecte des données a commencé lors de la réalisation de séquences pédagogiques avec des élèves ingénieurs en collaboration avec ces deux PME. L'objectif de ses séquences pédagogiques est de réaliser un diagnostic stratégique de l'entreprise. Suite à ce travail de diagnostic, nous avons analysé les données présentées par les étudiants (pré-codifiées) et repéré les thèmes principaux susceptibles d'expliquer le niveau de performance de l'entreprise. La comparaison de cette analyse avec les affirmations théoriques autour des notions de création de valeur, de terroir et du capital immatériel nous a permis de préparer nos entretiens approfondis.

Nous avons donc réalisé un premier entretien semi-directif approfondi (de deux heures et demie) avec les deux chefs d'entreprise en 2008 et en 2009. Mené sur la base d'un guide d'entretien comportant plusieurs volets : la présentation générale de l'entreprise, sa stratégie, son caractère territorial, sa performance et un focus sur le dirigeant. Deux autres entretiens furent réalisés en 2011 et 2012, avec un guide d'entretien similaire à celui utilisé en 2008 et 2009. Nous avons enregistré et retranscrit ces entretiens.

Par ailleurs, cette recherche s'est également nourrie de nombreuses rencontres et réunions formelles et informelles que nous avons eues avec les deux dirigeants (cf. tableau 1). Ces derniers nous sollicitent régulièrement pour réaliser des missions pour le compte de l'entreprise.

Dans cette étude, nous avons privilégié l'analyse des données primaires, en accordant aux données secondaires un rôle le plus souvent confirmatoire. La collecte des données s'est réalisée entre juillet 2008 et fin 2013. 35 pages de verbatim pour la PME COP et 26 pages pour la PME FAM furent exploitées.

Tableau 1 : Méthode de collecte de données

Données observées	Données orales	Données écrites
Ressources et compétences	Entretien semi-directif	Documents financiers
Gouvernance de l'entreprise	Entretiens informels	Rapports (de diagnostic)
Gammes de fabrication	En face à face	Compte rendu de mission

2.2. Description de l'organisation générale des deux PME

L'agroalimentaire auvergnat mise sur le volet terroir de ses produits (Mauvy, 2014). L'Auvergne, avec ses 5 fromages AOP, fabrique le quart de la production de fromage AOP en France. Dans ce qui suit, nous présentons successivement la COP et la FAM.

2.2.1. COP, une coopérative de terroir

a) Organisation et dirigeant

La COP est spécialisée dans la production du Cantal (sous AOP). Le marché de cette AOP connait des difficultés structurelles, baisse des prix et perte de 25% de part de marché en 2009 et 2011. Sa production est de l'ordre de 1200 tonnes pour un chiffre d'affaires (CA) de 7.5 millions d'euros. Elle emploie 35 salariés, possède deux sites de production et 5 sites d'affinage. Les conditions de production dans le premier site, réservé au lait cru, ne répondent pas à l'ensemble des exigences de l'IFS (International Food Standard). Le second, récemment rénové, est réservé au lait pasteurisé. La vente des fromages affinés représente 75% des ventes et celle des fromages en blanc (vendue à un affineur) représente 25% des ventes.
Cette entreprise assure la collecte de lait, la production et l'affinage des fromages et apporte un appui technique à ses adhérents. En 2008 cette coopérative a recruté des fromagers et a engagé un plan formation important. Elle rassemble environ 90 coopérateurs (producteurs) sur une zone de 50 km^2 de la région auvergnate. La majorité écrasante des producteurs s'est engagée dans l'appellation.

M. Clément, directeur de cette coopérative et âgé de 49 ans, est titulaire d'un bac+5 en management et en économie territoriale. Après de nombreuses années d'expérience dans les administrations publiques des régions voisines, il s'est lancé dans l'entrepreneuriat, chez COP, en 2004.

La COP a deux organes de gouvernance : le conseil d'administration et le comité exécutif. C'est le comité exécutif qui est le véritable décisionnaire de la PME. Toutefois, c'est au directeur de la coopérative de proposer une vision stratégique chaque année. « Cela me permet de prendre du recul et d'orienter les choix stratégiques » précise M. Clément[2]. Ce dirigeant regrette le regard qu'il qualifie de «court-termiste» de beaucoup de coopérateurs. Notamment, lorsqu'il s'agit d'investir dans l'immatériel ; i.e. développer une marque propre par exemple. Il note par ailleurs que la relation de confiance réciproque qu'il entretient avec le président facilite beaucoup la prise des décisions importantes et lui –dit-il- « transmet une certaine légitimité territoriale ».

b) Mécanismes de création de valeur dans la COP

La coopérative met sur le marché plusieurs produits avec trois niveaux d'exigence en matière de la qualité des produits. M. Clément est persuadé que pour la COP, il est crucial de développer un produit pour porter la marque propre et ainsi exister sur le marché durablement de manière différenciée. Ce produit, Fromarc, constitue un « gros tiers de nos ventes » précise M. Clément (i.e. 430 tonnes). Il est vendu sous MDD (marque de distributeur) à une grande enseigne de la GMS (grandes et moyennes surfaces). Au regard des efforts engagés par les coopérateurs et de ceux de la COP, les produits certifiés Bio[3] font partie de cette catégorie de produits exigeants en matière de qualité. Ils représentent 40 tonnes et sont écoulés auprès de magasins spécialisés. « Même si ce produit est moins rentable que le Fromarc, … la marge nette dégagée est satisfaisante », note M. Clément. Ce dirigeant souligne que la COP a opté, en matière de gamme de fabrication, pour une « maturation longue qui colle aux us et coutumes de la région et qui a un effet positif sur la qualité de fromage. »

[2] Nous avons consulté ce document pour l'année 2009.
[3] Certifié par une entreprise spécialisée, Ecocert.

La deuxième source de revenus est constituée de produits « Standards affinés au lait cru » pour un quart de la production, vendu aux grossistes. Et enfin les « produits standards pasteurisés et non affinés » pour 450 tonnes vendus aux affineurs et aux industriels.

M. Clément rappelle que la coopérative de par ses statuts a l'obligation de collecter du lait chez l'ensemble des producteurs. De ce fait, pour tirer la qualité des produits vers le haut, la coopérative a créé une association (ASSOCI) pour gérer au mieux son image et sa marque propre, i.e. son capital immatériel. Elle établit un cahier des charges exigeant et garantit une rémunération supplémentaire aux adhérents (6% des ventes) qui répondent aux exigences en matière de qualité. Ces adhérents doivent s'acquitter d'une cotisation de 10 € et d'un droit d'entrée qui est proportionnel au volume vendu à la coopérative. Il était important de créer cette association signale M. Clément, car « devant un jury de dégustation, nos fromages sont meilleurs par le goût et l'onctuosité mais moins bon en aspect (croutage) et en texture. D'où l'importance que cette qualité gustative soit portée par une marque propre. »

Par ailleurs, la COP a créé une SAS (Société par Actions Simplifiées), SOCCO, pour commercialiser l'ensemble de ces produits.

2.2.2. FAM, une PME familiale de terroir

a) Organisation et dirigeant

La FAM emploie 50 personnes et a réalisé un chiffre d'affaires de 15,8 millions d'euros en 2010. Cette SAS familiale, créée en 1928, est spécialisée dans la fabrication de Saint Nectaire. Mono-produit et leader sur son marché, 90 % de produits sont vendus sous AOP, ce qui lui permet de réaliser des économies d'échelles importantes. L'activité de l'entreprise est saisonnière, avec des collectes du lait concentrées sur 4 mois par an. En revanche, la demande reste constante sur l'année.
Le coût du lait représente 70 % du coût de revient, ce qui réduit la marge de manœuvre du dirigeant en matière de génération de revenus.

En 2005, M. Valex, le chef d'entreprise âgé de 47 ans, a racheté –à son père- le fonds de commerce et a repris l'entreprise. Il a un style de management qu'il qualifie de directif. Il considère son entreprise de par son processus de fabrication comme une entreprise traditionnelle et de terroir. Avec une formation de BTS commercial et plusieurs formations professionnalisantes, il se considère comme autodidacte.

Il s'appuie pour gérer l'entreprise sur un petit comité informel, constitué de trois cadres attachés à la région : responsable de personnel et de fabrication, responsable d'affinage et de la production fermière, responsable de collecte. Ce comité, selon M. Valex, représente « une des richesses principale de l'entreprise ». Il précise que lors des recrutements, l'attachement à la région constitue pour lui un atout important pour le candidat. Une des sources majeure de fierté qu'a ce dirigeant est de participer activement au développement économique local, en employant une cinquantaine de salariés locaux, « sans compter les producteurs de lait » souligne-t-il. C'est ce qui explique le peu de turnover dans cette entreprise.

b) Mécanismes de création de valeur dans la FAM

Dans un ton démonstratif M. Valex explique que la gamme de fabrication semi-artisanale, a un impact important sur la qualité des produits. Il insiste sur la préservation du savoir-faire régional en matière du traitement physique du lait. D'ailleurs ce dirigeant s'interdit de recruter des fromagers « intérimaires » considérant que c'est une activité clé pour l'entreprise. De plus il souligne l'effort important de l'entreprise en matière de formation dans les technologies alimentaires, en hygiène et sécurité alimentaire.

La moitié du CA est valorisée en MDD de terroir auprès de cinq grandes enseignes nationales. Cette voie de distribution est privilégiée par M. Valex car elle permet une meilleure valorisation des produits. De plus, le nom de l'entreprise figure sur l'étiquetage et la qualité est tirée vers le haut à travers le respect des normes IFS par exemple. Ce qui rassure et donne une certaine visibilité aux consommateurs sur l'origine du produit et permet à la PME de réaliser des économies en matière des dépenses de communication.

M. Valex nous confie que son observation des tendances de consommation, à travers le nombre important d'appels d'offres lancés par les distributeurs pour avoir des fromages « bio », lui permet de noter que le consommateur souhaite « du naturel ». Par conséquent, l'entreprise verse une prime de 25 % supérieur au prix pratiqué pour le lait conventionnel à tous les fournisseurs qui adhèrent à cette logique. De plus, M. Valex souhaite que l'entreprise soit perçue comme une entreprise citoyenne.
Pour ce qui est de l'innovation, le dirigeant nous explique que « les petites innovations[4] que nous mettons sur le marché concernent généralement les formats (…), car la qualité des produits (…) dépend notamment des outils de production, de la technologie utilisée, de la qualité du lait collecté et du savoir-faire des collaborateurs. » Ce dirigeant note qu'il existe un différentiel de 15% entre le premier prix et celui le mieux valorisé au sein de l'appellation.

Enfin, un des atouts majeurs de la FAM, selon M. Valex, est que l'entreprise fonctionne comme une coopérative dans la mesure où il s'impose de collecter le lait chez l'ensemble des producteurs de sa zone. Cette manière d'agir crée un climat de confiance entre le dirigeant et ses fournisseurs.

3. Analyse Et Discussion Du Cas : Capital Immateriel Et Ancrage Territorial Renforcement Reciproque

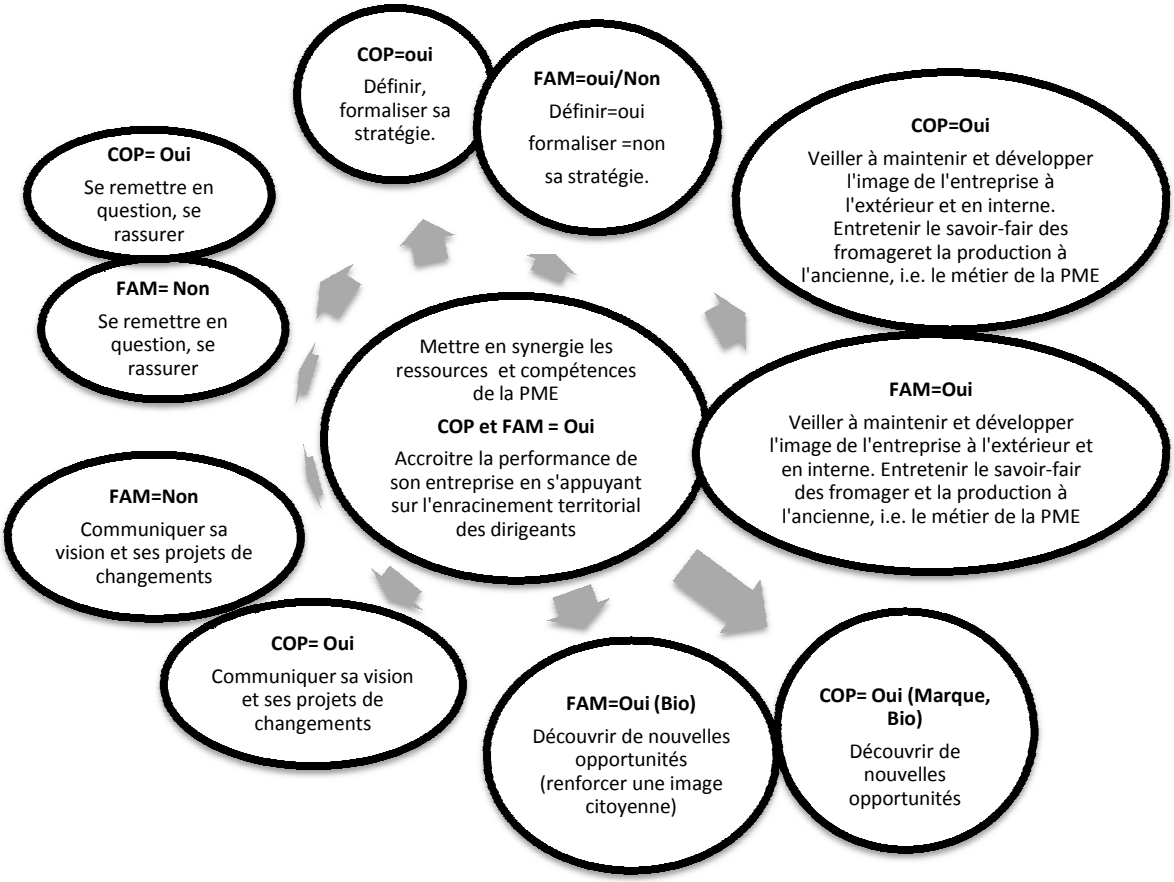
Dans ce qui suit nous présentons d'abord le rôle du capital humain adossé à l'ancrage territorial (3.1) et analyserons par la suite le lien du capital organisationnel et relationnel avec l'ancrage territorial des deux PME (3.2).

3.1. L'ancrage territorial et les qualités managériales des dirigeants jouent un rôle déterminant dans la création de valeur des deux PME

Le capital humain et notamment le capital dirigeant combiné à l'attachement territorial parait, dans les deux PME, impactant (cf. schéma 2).

[4] Il s'agit d'innovations incrémentales au sens du Manuel d'Oslo (OCDE, 2005).

Schéma 2 : Description du volet capital dirigeant à travers des activités managériale et entrepreneuriale des deux dirigeants



Les deux dirigeants adoptent deux styles de management différents. Le directeur de la COP, ne bénéficiant pas d'une forte légitimité territoriale compense ce manque de reconnaissance territoriale par des objectifs économiques ambitieux. Il propose une vision stratégique –formalisée- pour la coopérative. Il propose la création de la marque propre et s'engage sur le marché Bio. Alors que le dirigeant de la PME familiale bénéficiant à la fois d'une forte légitimité territoriale et concurrentielle ne formalise pas sa vision stratégique et considère que le dirigeant doit être capable de comprendre et anticiper les grandes tendances de consommation. On peut qualifier les deux dirigeants d'entrepreneurs-entreprenants, au sens de Marchesnay (2001b). Opportunistes, ils cherchent à comprendre les tendances de consommation et à adapter les produits aux clients potentiels. Cela est particulièrement perceptible lorsque les deux dirigeants visent à davantage investir le marché Bio. Les raisons nous paraissent quelque peu différentes dans les deux PME. Pour la FAM, ce marché permettra le développement d'un capital image (i.e. capital relationnel) autour de l'entreprise citoyenne. La prime de 25% accordée aux producteurs adhérant à cette démarche montre clairement cette volonté du dirigeant.

En revanche, pour le directeur de la COP investir ce marché lui permet de se distinguer du groupe stratégique de l'appellation avec une marge nette plus élevée que les produits AOP standards. En revanche, étant un acteur de l'économie sociale et solidaire l'image de l'entreprise citoyenne semble acquise de par les statuts et le fonctionnement de la coopérative.

Les deux dirigeants sont attachés au territoire. Pour le dirigeant de la FAM, l'attachement est affectif ; natif de la région un contrat tacite et social le lie avec les habitants du village. De plus, ce dirigeant adopte une préférence locale lors de recrutement de ses collaborateurs.

Alors que le directeur de la coopérative estime avoir une légitimité concurrentielle de par les choix stratégiques (formalisés) et s'appuie sur le président de la coopérative pour bénéficier d'une certaine légitimité territoriale (cf. tableau 2).

Tableau 2 : Rôle primordial du capital humain dans le processus de création de valeur des deux PME

Capital immatériel	Efforts (actions) de l'entreprise - FAM-	Potentiel de valeurs économiques – FAM-	Efforts (actions) de l'entreprise COP	Potentiel de valeurs économiques – COP -
Capital humain				
Capital dirigeant				
Qualités managériales du dirigeant	Préférence territoriale en matière de recrutement collaborateurs	Climat de confiance et de sérénité. Forte légitimité territoriale	Travail en concertation avec le président de la coopérative (qui bénéficie d'une forte légitimité territoriale)	Confiance, attachement aux valeurs de l'entreprise. Une certaine légitimité territoriale.
	Mono-produit Entrepreneur entreprenant (Stratégie de distinction)	Economies d'apprentissage Légitimité concurrentielle	Création de marque propre Plusieurs produits Entrepreneur entreprenant (Stratégie de distinction)	Forte légitimité concurrentielle (remplit son rôle économique)
Capital Collaborateurs				
Savoir-faire des fromagers	Plan de formation Stagiaires	Compétences clés de l'entreprise. L'attachement au territoire constitue un atout supplémentaire	Plan de formation Stagiaires	Compétences clés de l'entreprise. Le caractère transférable de ses ressources peut être considéré comme une menace forte !
Fidélité des salariés	Bonnes conditions de travail Caractère judicieux des recrutements	Capital collaborateurs important (sérénité, motivation, peu de turnover)	Conditions de travail plutôt satisfaisantes Difficulté de recruter, l'imprégnation territoriale du candidat n'est pas nécessaire.	Capital collaborateurs pas suffisamment nourri et exploité Doit être renforcé par un effort en matière de communication interne sur les choix stratégiques.

Quant au capital collaborateurs, la FAM bénéficie de l'enracinement territorial des trois cadres dirigeants et de leur expertise. Il s'agit certainement d'un capital, créé par une action, au sens de Thésaurus V1 (2011), engagée à travers une politique de recrutement « localisée ». Le savoir-faire des fromagers nourri par des investissements importants en formation au sein de cette entreprise familiale augmentent la fidélisation des salariés et rendent ces ressources stratégiques, au sens de Koenig (1999). Pour ce qui est de la COP, le directeur a bien souligné l'importance de l'investissement en formation nécessaire au développement et au maintien du savoir-faire des fromagers. Dans les deux cas le peu de turnover laisse penser que les deux équipes dirigeantes ont réussi à créer des conditions de travail propices à une fidélisation des collaborateurs. Le tableau 2 propose une synthèse du rôle majeur du capital humain dans le processus de création de valeur.

3.2. Capital organisationnel et capital relationnel adossés à l'ancrage territorial

Le fort ancrage territorial des deux PME est représenté entre autres par des labels des produits, lesquels constituent des droits (i.e. capital immatériel). Ces labels permettent à ces PME de se distinguer de l'ensemble du groupe stratégique de terroir (cf. tableau 3).

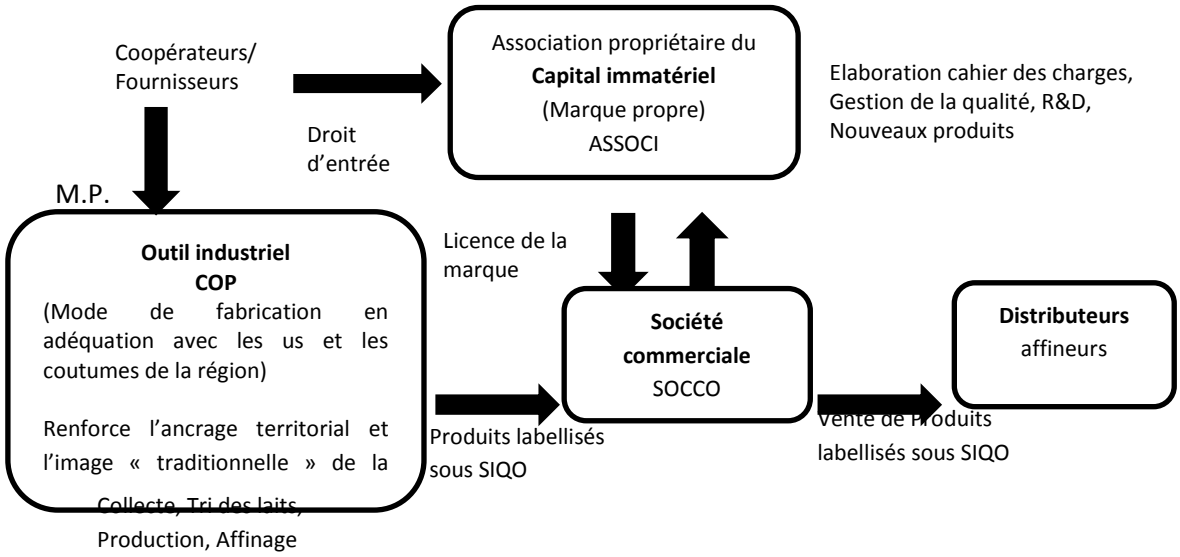
Tableau 3 : Le capital organisationnel et les capitales relationnelles sources de distinction des deux PME

Capital immatériel	Efforts (actions) de l'entreprise FAM	Valeurs (ou potentiel de valeurs économiques) créées	Efforts (actions) de l'entreprise COP	Valeurs (ou potentiel de valeurs économiques) créées
Capital organisationnel				
Processus de fabrication, d'innovation, de décision	Entretien de la gamme de fabrication à l'ancienne	Image de la production à l'ancienne (ou traditionnelle). Potentiel de distinction du groupe stratégique de terroir. Qualité organoleptique irréprochable des produits	Développement d'une gamme de fabrication qui colle aux us et coutume de la région (Maturation longue des fromages)	Image de la production à l'ancienne (ou traditionnelle). Image de « Terroir » consolidée Potentiel de distinction du groupe stratégique de terroir. Qualité organoleptique irréprochable des produits
Processus combinatoire des ressources (connaissance du métier du dirigeant et le savoir-faire des collaborateurs)	Processus complexe qui contient l'agencement évolutif du système de ressources matérielles et immatérielles	Rentes quasi-ricardiennes Image de « Terroir » consolidé Compétences spécifiques (rares et difficile à imiter)	Création d'une entité pour gérer le capital immatériel	Multiplication des sources de revenus. Rentes quasi-ricardiennes Compétences spécifiques en raison de la systémisation de la gestion du capital immatériel
Capital relationnel				
Capital relationnel (fournisseurs).	Collecte de lait dans l'ensemble de la zone (plutôt un atout).	Image d'une entreprise responsable et solidaire. Fidélité des fournisseurs Image de terroir. Produits « typés » et de qualité. Rentes ricardiennes (à l'ensemble de la zone)	Collecte de lait dans l'ensemble de la zone (obligation statutaire).	Image d'une entreprise responsable et solidaire (obligation statutaire). Fidélité des fournisseurs/propriétaires. Image de « Terroir » Produits « typés » et de qualité. Rentes ricardiennes (à l'ensemble de la zone) Quasi-rentes ricardiennes
Capital relationnel (clients)	IFS exigé par les clients, notamment GMS Prime pour les produits « Bio ». Pas de possibilité de créer une marque propre.	Capital relationnel consolidé (en répondant aux exigences des clients), permet d'écouler un volume important Distinction par rapport au groupe stratégique de terroir	Réactivité vis-à-vis des souhaits de la GMS (pas d'IFS). Prime pour les produits marketés et « Bio ». Création de la marque propre	Routines organisationnelles efficientes pour répondre aux clients exigeants. Tire la qualité vers le haut Fidélité des clients Distinction par rapport au groupe stratégique de terroir

Les sources de revenus de la COP diffèrent par le niveau d'exigence en matière de la qualité de la matière première et du temps d'affinage qui dépasse largement les exigences de l'appellation.

Aussi la création de l'association ASSOCI permet de rendre visible le capital immatériel (i.e. la marque propre) issu de l'investissement des adhérents, de rémunérer de manière équitable l'ensemble des adhérents (en fonction de leur implication) et d'instaurer une gestion systématique du capital immatériel. Cet investissement prend la forme de cotisation, de droit d'entrée et des efforts en matière de la qualité de lait collecté (cf. schéma 3). De plus, de par ses statuts, la COP a un capital relationnel fort avec ses adhérents.

Schéma 3 : Organisation de l'architecture de la valeur chez COP



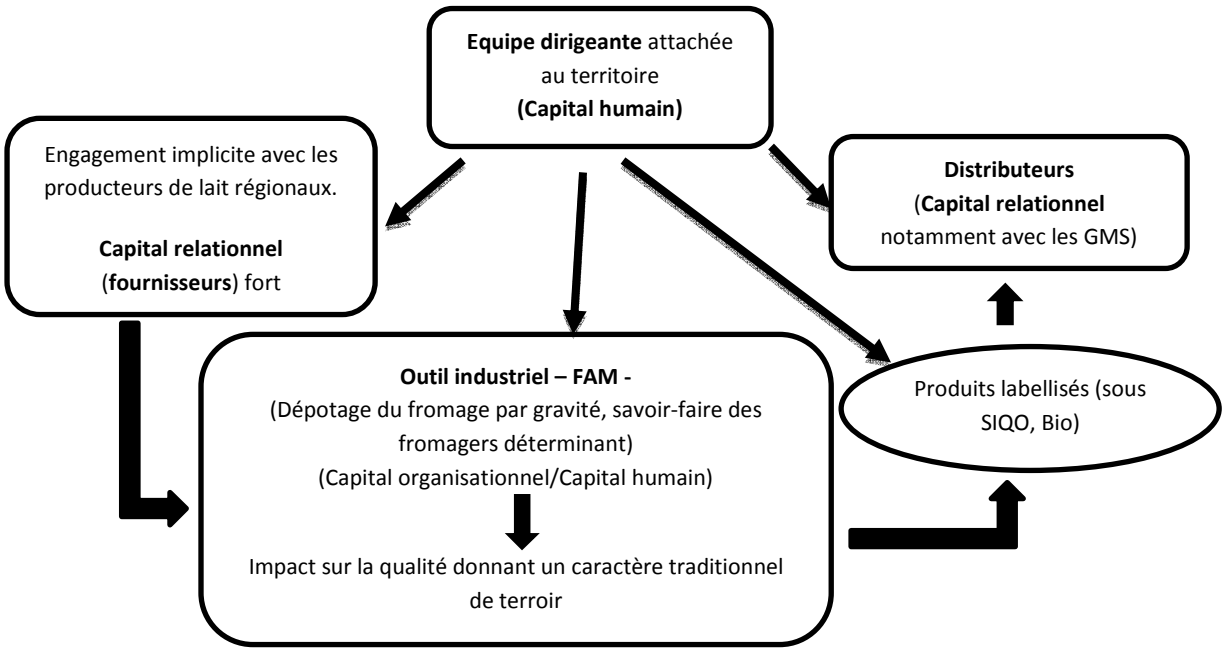
Pour ce qui est des clients, le directeur considère que la fidélité de la grande enseigne nationale s'explique par sa disponibilité et la réactivité de la COP, sans oublier la qualité des produits.

Quant au mode de fabrication, M. Clément le considère en adéquation avec les us et coutumes de la région. Cette façon de produire renforce le capital organisationnel et a impact positif sur l'image que dégage l'entreprise consolidant ainsi son capital relationnel. Une société commerciale (SOCCO) fût créée pour développer un savoir-faire en matière commerciale. Ces trois entités organisent la création et la répartition de la valeur entre les parties prenantes (cf. schéma 3).

La FAM, quant à elle, met en avant son capital organisationnel ; i.e. un agencement particulier des équipements matériels, de façon à dépoter le lait à l'ancienne (cf. schéma 4). Ce processus de fabrication a un impact positif sur la qualité des produits et sur son image.

Ces ressources spécifiques, i.e. difficilement redéployables dans d'autres contextes, engagées et combinées dans le processus de création de valeur permettent de dégager des rentes de type ricardien (Koenig, 1999). La valeur créée trouve de ce fait son origine dans l'agencement du savoir-faire des fromagers, de la connaissance du métier des cadres dirigeants et leur enracinement territorial, du processus de fabrication à l'ancienne, de la relation de confiance avec les fournisseurs. Pour ce qui est des clients, un pragmatisme réciproque entre les GMS et la FAM justifie le renforcement de son capital relationnel. Pour les premiers il s'agit de bénéficier d'une image d'un acteur responsable et local bénéficiant ainsi d'un transfert de légitimité territoriale (Beylier, Messeghem et Fort, 2011), alors que pour la PME FAM cette collaboration permet d'écouler un volume de produits important et de tirer la qualité des produits vers le haut.

Schéma 4 : Organisation de l'architecture de la valeur chez FAM



Ce système de ressources – au sens de Koenig (2001) - est évolutif et confère à cette entreprise son caractère distinctif avec des compétences difficilement imitables.

Conclusion

Le cas de deux PME agroalimentaires de terroir constitue le support central de cette recherche. Nous avons montré que le capital immatériel représente une force considérable de singularité sur le marché pour les deux PME à fort ancrage territorial. La coopérative a séparé, par une démarche entrepreneuriale, une bonne partie du capital immatériel, alors que l'entreprise familiale tente de développer son image à travers un système de ressources qui rappelle son enracinement territorial.
Soulignons ici que notre réflexion comporte des limites que l'on peut résumer :

- elle n'a pas vocation à être généralisée (sans être nuancée) à l'ensemble des PME de terroir et encore moins à des PME ;

- elle se contente des déclarations des dirigeants d'entreprise.

Malgré ces limites, retenons un enseignement managérial majeur, les actions stratégiques des deux PME sont pensées autour de cet ancrage territorial et du capital immatériel. Il parait donc primordial d'identifier le capital immatériel dans ce type d'entreprise pour pouvoir le gérer de manière systématique.

Abstract

This paper presents the main natural disasters risks in Romania, the financial solutions to fight against natural disasters and analyses using a direct research method the way in which the role played by different entities in the protection and recovery following natural catastrophes is perceived in Romania. The main objectives of the direct research were studying the perception of natural risks and of protection instruments, as well as the perception regarding the quality of the relationship between the main stakeholders: public authority, population, and insurance companies. The survey results indicate that in Romania the risks perceived as the most dangerous are earthquake and floods. The main role in fighting natural catastrophes is played by local authorities, but the perception is that the central authority as well, the insurance companies, the population and the EU institutions are important in the prevention and recovery following natural catastrophes.

Keywords: natural risks management, perception of natural risks, insurance, survey, Romania.

Introduction

In this paper we aim at studying using a direct research the way in which the role played by different entities in the protection and recovery following natural catastrophes is perceived in Romania. The public authorities play an important role in the prevention of risks, and also in case of the occurrence of the natural risk (evacuation, shelter etc.).

Romania has a National Strategy for Flood Risk Management for medium and long term, for 2010-2035, elaborated in concordance with the Directive 2007/60/CE of the European Parliament and of the Council on the assessment and management of flood risks. The strategy sets out clearly for the next years the legal, institutional and technical framework to mitigate the adverse consequences of floods on: socio-economic activities, assets (land and dwellings), human health and environment (Negru and Neamtu, 2014). The strategy aims to prevent and reduce the consequences of floods on socio-economic activities, life and human health and environment through coordinated, inter sectorial actions. The strategy is part of an integrated water and resources management and contains a set of principles, but also specific economic, social and environmental objectives, concrete actions and the plan to implement the strategy. This strategy defines also the specific responsibilities of central and local authorities and of the population.

Moreover, the climate change considerations are presented in the National Strategy on Climate Change, which explains two key elements: the prevention and combating of climate change (through actions aimed at reducing the emissions of greenhouse gases) and the adequate adaptation with minimal damage to the existing climate changes. The strategy includes a chapter dedicated to water resources and also one for insurance, highlighting the importance of mandatory home insurance.

The financial solutions in Romania to fight against natural disasters can be structured in ex-post financing instruments, such as the Intervention Fund, budget reallocation, international funds, European Union Solidarity Fund, domestic and/or external credit, donor assistance, and ex-ante financing instruments, among which home insurance, mandatory and/ or optional insurance.

In Romania, the financial protection against natural catastrophes is realised by a mix of compulsory insurance and of State intervention in case of damage. The most widespread solution in Europe is the case in which the State's intervention is totally absent and most of the covers relating to natural hazard are optional (CEA, 2007). The rate of penetration of these covers varies according to the risk perception and to the effective risk exposure.

Among the ex-post sources of financing natural disaster there is the Intervention Fund, which is allocated for the financing of urgent action, for counteracting the effects of natural calamities and for the support of affected persons. The Intervention Fund can be increased by the government over the years with amounts from the Reserve budgetary fund for assuring the amounts for the counteracting of the effects of natural catastrophe.

Other ex-post sources of financing are the loans from international financial institutions, for rebuilding the damaged infrastructure.

As a member of EU, for Romania a very important fund in the recovery after large scale natural disasters is the European Union Solidarity Fund (EUSF). The European Union Solidarity Fund (EUSF) was set up to express European Union solidarity to disaster-stricken regions within Europe in an efficient and flexible manner. The EUSF was created in 2002, after the massive floods from the Central Europe and since then 24 different European countries have received aid for an amount of over 3.784 billion € (European Commission, 2015).

The main ex ante financing instrument is the mandatory home insurance. In Romania, according to the Law 2602008 homeowners must insure their buildings against three natural risks: flood, earthquake and landslide risk. There are fines for the homeowners for not having mandatory home insurance and the fines are the responsibility of local public authorities. The law supposed to motivate homeowners to reduce the risk, because the government does not provide financial compensation to homeowners to rebuild their properties after disasters related to floods, earthquake and landslide. In Romania, the insurance industry has developed after the fall of the communism in 1989 and even if the starting point of the Romanian insurance market was very low (Petrescu, 2005), today the supply on the Romanian insurance market is diversified and the potential of the Romanian insurance market is high.

Natural disasters risks in Romania

There are many natural hazards: earthquakes, floods, storms, landslides, drought and extreme temperature, which are causing important losses in Romania. The seismic risk is a significant natural risk in Romania in terms of economic damages and population affected.

The seismicity of Romania is clustered in several epicentral zones: Vrancea, Făgăraş-Câmpulung, Banat, Crişana, Maramureş and South Dobrogea. There are also epicentral zones of local importance in Transylvania, in the area of Jibou and Târnava River, in Northern and Western part of Oltenia, in Northern Moldavia and in the Romanian Plain (National Institute for Earth Physics, 2016).

In the case of earthquakes the economic losses can be especially high because densely populated areas are affected and the infrastructure and the residential buildings present a high vulnerability to seismic risk. The capital of Romania, Bucharest is considered as one of the capitals with the highest seismic risk.

The event with the most severe consequences was the 1977 earthquake, which killed 1641 persons and the statistics indicate that the amount of total damage was of more of 2 billion $ (Guha-Sapir, D.

Below, R. and Hoyois Ph., 2015). The World Bank loss estimation after the 1977 earthquake indicates that from the total loss of 2.05 Billion US $ more than 2/3 was in Bucharest and the magnitude of direct loss and indirect consequences of loss explain the concern of civil engineers and government for assessment and reduction of seismic risk in Romania (Lungu D. et al. 2004).

However, the most frequent disasters with important economic losses were related to floods. As far as flood risk is concerned, 1028000 ha of land are exposed to flooding, 928935 citizens live in high flood risk areas and 903 localities are situated in high flood risk areas (Romanian Waters National Administration, 2013). Floods are a devastating phenomenon and in this century there were major floods and in 2005, 2008, 2010 and 2014 floods have affected large areas and the country received aid from the European Union Solidarity Fund.

Estimating the future impacts of flooding in view of socio-economic and climate changes Rojas et al. (2013) indicates that Czech Republic, Romania and especially Hungary will likely experience large flood damages by the end of this century and the United Kingdom, France and Italy in Western Europe as well as Romania, Hungary, and Czech Republic in Eastern Europe show the highest absolute damage estimates and are likely to bear the highest costs of adaptation.

Objectives and methodological framework of the research

In the context of a larger research, we analysed the way in which the role played by different entities in the protection and recovery following natural catastrophes is perceived in Romania using a quantitative method of research. The market survey is the method of research used the most often and the most common instrument used to collect primary data is the questionnaire. Through the market survey, we aim at quantifying the information obtained.

The main objectives were studying the perception of natural risks and of protection instruments, as well as the factors influencing it, the perception regarding the quality of the relationship between the main stakeholders: public authority, population, and insurance companies.

The perception of roles of actors in protection and recovery following natural disasters in Romania was studied in May 2015 using a quantitative method of research. The population studied was formed by homeowners from Romania. According to the "Population and Households Census" (published by National Institute of Statistic) the records of the census data for the years 1992, 2002 and 2011 indicate a number of households of:7.666.181, 8.111.391 respectively 8.723.699.

The sample was calculated function of the formula (Cătoiu et al., 2009, p. 494):

$$n = \frac{t^2 * p * q}{e^2} \qquad [1]$$

where:
n = sample size,
t = t value of Student coefficient for the confidence level (in this case 1.96 for 95% confidence level),
p = the proportion of sample components that are characterized by a particular attribute (if we do not know the value of we consider p = 0.5, for which p*q is max),
q = 1-p
e = margin of error.

The sample size is of 461 people (homeowners), for a confidence level of 95% (t=1.96) and a margin of error of +/-4.56%.

The main rules applied when the research was conducted were: the participation was voluntary in all phases and the respondents were not mislead when required to cooperate. Another important principle is that the respondents are strictly anonymous and the confidentiality of data obtained

through direct marketing research is maintained. In the research there is a clear distinction between the results of the marketing research, and their interpretation by the researchers and the recommendations made on those grounds.

Analysis and interpretation of the information resulted from the research

In order to study the perception of risks among the population we asked the interviewed subjects to estimate the potential of disaster in Romania in terms of human and economic damages for earthquake, floods, landslide, drought and heavy snow. We have used the semantic differential scale: very high risk=5, very low risk=1. In the opinion of homeowners the risks perceived as the most dangerous are earthquake (3.69) and floods (3.51) – see Table 1.

Table 1: Opinions of respondents regarding the potential of disaster of natural risks

	earthquake	floods	landslide	drought	heavy snow
VERY HIGH RISK	36.44%	24.95%	8.68%	9.76%	14.75%
HIGH RISK	21.69%	32.54%	24.95%	19.09%	19.09%
MEDIUM RISK	23.21%	21.26%	31.45%	31.89%	24.95%
LOW RISK	11.71%	11.50%	25.81%	25.16%	25.81%
VERY LOW RISK	6.94%	9.76%	9.11%	14.10%	15.40%
Score	3.69	3.51	2.98	2.85	2.92

In the opinion of the subjects interviewed the main role in fighting natural catastrophes is played by: local authorities (3.46), but the perception is that the central authority as well (3.34), the insurance companies (3.27), the population (3.24) and the EU institutions (3.05) are important in the prevention and recovery following natural catastrophes – see Fig. 1.

.

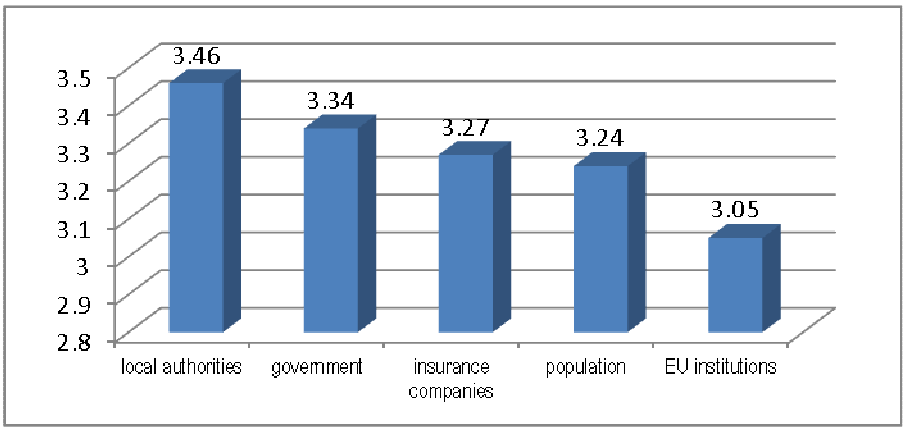

Fig. 1: Perception of the role in preventing and reconstruction after natural catastrophes

As far it concerns the importance of different measures in the prevention of natural catastrophes the answers indicate that the measures considered with high importance in the prevention of the natural catastrophes are: building new constructions respecting security norms (4.48), consolidating existing buildings (4.34), legislative restrictions regarding deforestation (4.24), reforestation measures (4.20), damming (4.12) and insurance of properties (3.81) – see Fig. 2.

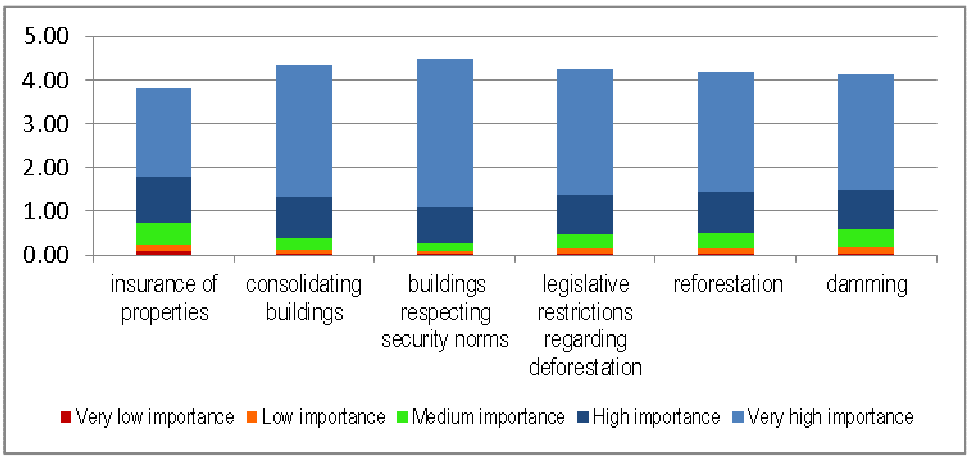

Fig. 2: Importance of different measures in the prevention of the natural catastrophes

67.90% of the subjects consider that the construction of new buildings respecting security standards is very important in the prevention of natural catastrophes, 20.61% consider it important and only 5.42% appreciate that the measure is of low or very low importance. In the case of the insurance of properties, 40.56% consider it very important, 26.25% consider it important and only 16.70% consider that the insurance of buildings is with low or very low importance in the prevention of natural catastrophes.

The opinions regarding the measure in which the local authorities, government, insurance companies, homeowners and EU institutions are prepared to fight natural catastrophes was studied using the semantic differential scale (very well prepared = 5, not well prepared = 1). As far as the measure in which they are prepared to fight natural disasters is concerned, the answers indicate that EU institutions are considered to be well prepared to face the natural catastrophes (3.33), insurance companies are perceived as being prepared to fight natural catastrophes (3.05) while the government, population and local authorities are not considered well prepared to fight natural catastrophes.

.

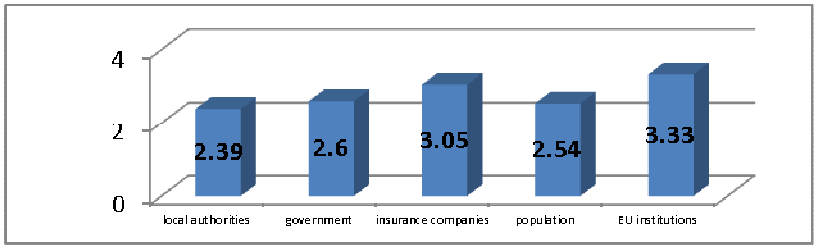

Fig. 3: Measure in which the local authorities, government, insurance companies, homeowners and EU institutions are prepared to fight natural catastrophes

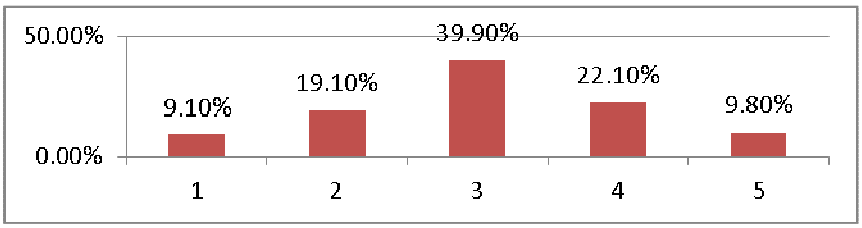
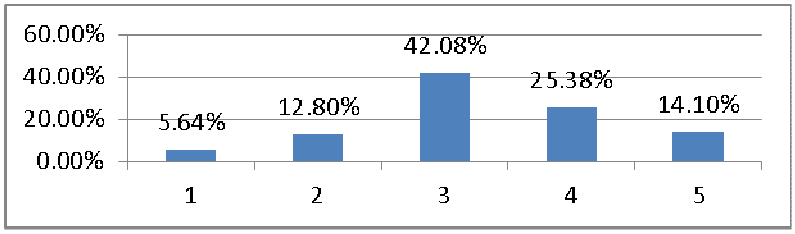
Regarding the general perception on the activity of insurance companies in Romania related to natural disasters, 31.90% of respondents have a favourable opinion. The score of 3.044 on the scale 1 (Not at all favorable) to 5 (Very favorable) indicate a slightly favorable opinion.



Not at all favorable=1, Very favorable=5

Fig. 4: Perception of the activity of insurance companies related to natural disasters in Romania

The general opinion regarding the collaboration between homeowners, public authority and insurance companies in the case of the mandatory home insurance is favorable (3.3).



1=Not at all favorable, 5= Very favorable

Fig. 5: Perception of the collaboration between the homeowners, public authority and insurance companies

Then, we asked the homeowners to evaluate in the case of mandatory home insurance the bilateral relationships between the public authority, insurance companies and population (very poor = 1, very good = 5). Even if the general opinion regarding the collaboration between homeowners, public authority and insurance companies is favorable, the relationships among the population and insurance companies, the relationships among public authority and insurance companies and the relationships between population and public authority are not perceived as good.

The results of the surveys indicate that in the opinion of homeowners the risks perceived as the most dangerous are earthquake and floods.

The main role in fighting natural catastrophes is played by: local authorities, but the perception is that the central authority as well, the insurance companies, the population and the EU institutions are important in the prevention and recovery following natural catastrophes. Regarding the measure in which they are prepared to fight natural disasters, the respondents consider that EU institutions are well prepared, and the population, the local and central authorities are less prepared to fight natural disasters.

The premises for improving the activity of prevention related to natural risk are better cooperation and better communication among the public authorities, insurance companies and the population.

Abstract

This paper presents the main particularities of the home insurance market in Romania related to the protection against natural risks. Using direct research the situation of the mandatory home insurance as a tool in the protection against natural catastrophes is analyzed. The opinions of respondents from insurance companies and brokers regarding the mandatory home insurance are studied. The research showed that mandatory home insurance is perceived as being opportune by insurers. The survey results indicate that there is a need for facultative home insurance as well.

Keywords: natural catastrophes, mandatory home insurance, survey, Romania.

Introduction

In this paper we aim at outlining the situation of home insurance in Romania, and presenting the perception relative to the mandatory home insurance in Romania using the point of view of insurance specialists, from insurance companies and brokers.

The protection against natural catastrophes can be obtained using home insurance. In Romania, there is mandatory home insurance for protection against three natural risks: earthquake, floods and landslide (Law 260/2008) and there is, as well, optional home insurance, supplying protection for more risks.

The mandatory insurance of homes has been introduced in Romania in the context in which natural phenomena to be feared, such as floods, landslides, earthquakes can affect the population. There are three parties involved: the population (the potential insured), insurance companies and the authorities. According to Law 260/2008, homeowners in Romania have to purchase home insurance, and if they do not, they can be fined by local authorities. The mandatory home insurance provides cover in case of three natural phenomena: floods, landslides and earthquakes and according to the law, all natural persons and legal entities are required to insure against natural disasters all the homes in the rural or urban environment.

The premium and insured amount depends on the type of the constructions. There are two categories: the construction type A, with reinforced concrete resistance structure, metal or wood or with exterior walls made of stone, brick or any other material resulted from heating or chemical treatment and the construction type B with exterior walls made of other materials which have not undergone a chemical or heating treatment. For the constructions type A the insurance premium is 20 Euro and the insured amount 20000 Euro, and for type B the insurance premium is of 10 euro and the insured amount 10000 euro.

The first mandatory home insurance policy was issued in July 2010 and at the end of 2010, there were 2132778 optional home insurance contracts and 367287 mandatory (ASF, 2015). In 2011, there was the highest number of optional home insurance contracts: 4747280 and 574229 mandatory, which translates to a degree of insurance coverage of houses in Romania of about 63%. In 2014 the number of optional home insurance contracts has decreased to 2057208 and the number of mandatory home insurance has increased to 1491329 (ASF, 2015).

The potential of the Romanian insurance market is high due to a series of factors. The main factors are: the large number of people; Romania is on 7th place in EU function of the population, the geographical area, the size of the country places Romania in EU on the 9th position and due to the large number of properties. The real demand is quite low and since 2009 the economic crises have affected the insurance demand. The main factor affecting the demand is the low purchasing power of potential insured.

The insurance demand on the Romanian market is focused on geographical areas with a high economic potential and on the above-average income population. In 2014, 49.88% of gross insurance premiums were underwritten in the Bucharest well-developed from an economic point of view area (ASF, 2015).

The supply on the Romanian insurance market is diversified (Petrescu, 2009) and the insurance sector in Romania is integrated in the global economy. In Romania in 2010, at the beginning of the year (1st January) there were 45 insurance companies authorized to function and at the end there were 43 insurance companies (one company has entered in 2010 on the Romanian market and three companies left the market). In 2015, the number has decreased and there were 37 insurance companies authorized to function by the ASF, from which 27 companies with non-life insurance activity and 447 brokers. The mandatory home insurance can be closed by the 12 insurance companies authorized to close mandatory home insurance contracts from the Insurance Pool against Natural Disasters (PAID) and by other 11 authorized insurance companies, which have concluded agreements with PAID in order to supply the mandatory home insurance and handle the process of paying out claims.

Good regulation has the role to ensure competitive, solvent and fair markets in which all key stakeholders are adequately protected and to ensure that quality, reasonably priced products and services are available from reliable sources when needed (Liedtke, 2011). The research investigates if the regulation related to mandatory home insurance is, in the perception of specialists in insurance, a good one, adapted to the specific needs.

Objectives and methodological framework of the research

In order to study the perception in Romania of the home insurance as a tool of protection against natural catastrophes a survey was conducted on a sample of 117 companies specialized in insurance: insurance companies and brokers. The research was conducted based on a face-to-face interview with the help of a written questionnaire completed by the interview operator. Among the main objectives of the research were: the perception of main instruments in recovery and in protection against the risks, the perception of mandatory home insurance, the perception regarding the insurance premium and the sum insured for this type of insurance.

The hypotheses of the survey were established by starting from the results of a previous qualitative research which aimed at understanding and explaining various phenomena of insurance perceptions better. A qualitative research allows for a better understanding of the phenomenon investigated without appealing to quantifying (Cătoiu et al. 2009) and was realized in March-April 2014 using semi-directed interviews among insurance companies and authorities. From the interviews resulted that the main instruments used by the authorities in the prevention of natural catastrophes were: allocation of funds for the consolidation of existent buildings/infrastructure, building dams, consolidating riverbeds, reforestation and in recovery following natural disasters the main instruments used by the authorities were: allocation of funds for the reconstruction of damaged goods, giving help to the persons affected, taking the measures to obtain external funds. The answers from the qualitative research helped to design the questionnaire from the survey conducted in May 2015.

The direct research was conducted respecting the rules from the code elaborated by The International Chamber of Commerce (ICC) and by ESOMAR. The main rules applied were that the participation in the research was voluntary in all phases, the respondents were anonymous, the confidentiality was

maintained and there is a clear distinction between the results of the interviews and their interpretation by the researchers.

Analyze and interpretation of the information

In the opinion of the respondents the measures considered very important in the prevention of natural catastrophes are: new constructions respecting security norms (4.57), consolidating existing buildings (4.38), legislation regarding deforestation (4.36), allocation of funds for reforestation (4.22), allocation of funds for buildings dams, consolidating riverbeds damming (4.15) and insurance of existent buildings (4.10).

71.79% of the respondents consider that the construction of new buildings respecting security standards is very important in the prevention of natural catastrophes and 52.99% consider the insurance of buildings in the prevention of natural catastrophes very important (see Table 1).

Table 1: Importance of different measures in the prevention of the natural catastrophes

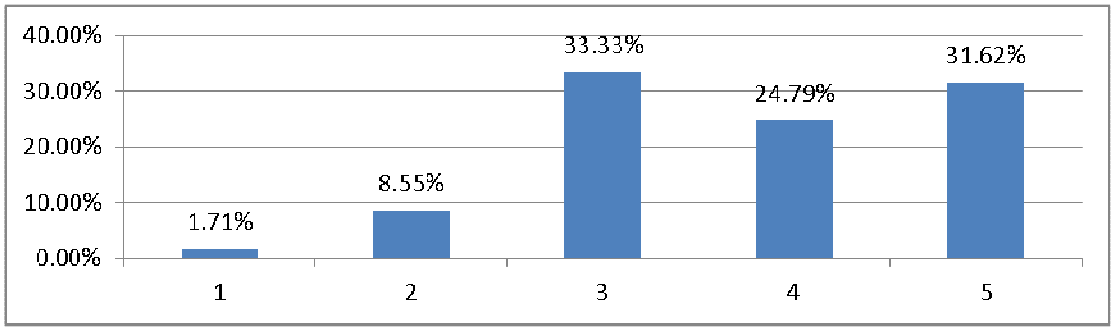
	insurance of properties	**consolidating buildings**	**buildings respecting security norms**	**legislative restrictions regarding deforestation**	**reforestation**	**damming**
Very low importance	5.13%	3.42%	1.71%	5.13%	4.27%	4.27%
Low importance	6.84%	2.56%	1.71%	2.56%	5.13%	7.69%
Medium importance	13.68%	7.69%	5.98%	11.11%	13.68%	14.53%
High importance	21.37%	25.64%	18.80%	17.95%	17.95%	16.24%
Very high importance	52.99%	60.68%	71.79%	64.10%	58.97%	57.26%
Score	4.10	4.38	4.57	4.36	4.22	4.15

The measures considered very important in the reconstruction after natural catastrophes are: compensation for the incurring loss from insurance companies (4.53), giving help to the persons affected (4.26) external funds (4.14) and allocation of funds from the State for the reconstruction of damaged goods (4.11) (see Table 2).

Table 2: Importance of different measures in the reconstruction after natural catastrophes

	Allocation of funds from the State for reconstruction	**payment of damages from insurance companies**	**giving help**	**external funds**
Very low importance	2.56%	1.71%	2.56%	4.27%
Low importance	5.98%	1.71%	3.42%	5.13%
Medium importance	11.97%	6.84%	10.26%	10.26%
High importance	36.75%	21.37%	32.48%	33.33%
Very high importance	42.74%	68.38%	51.28%	47.01%
Score	4.11	4.53	4.26	4.14

The respondents from insurance companies and brokers consider that in Romania the opinion regarding the activity of insurance companies in Romania related to natural disasters is favorable (3.76) – see
Fig. 1.



1=Not at all favorable, 5= Very favorable

Fig. 1: Perception of the activity of insurance companies in Romania related to natural disasters

The opinions regarding the mandatory home insurance were studied using the Likert scale. The respondents agree that mandatory home insurance is necessary (1.37), they consider that facultative insurance is more useful than mandatory home insurance (0.65) and they consider that the mandatory home insurance is very well adapted to the needs (0.13).

The respondents disagree that mandatory home insurance is sufficient for protection against natural disasters (-0.38).

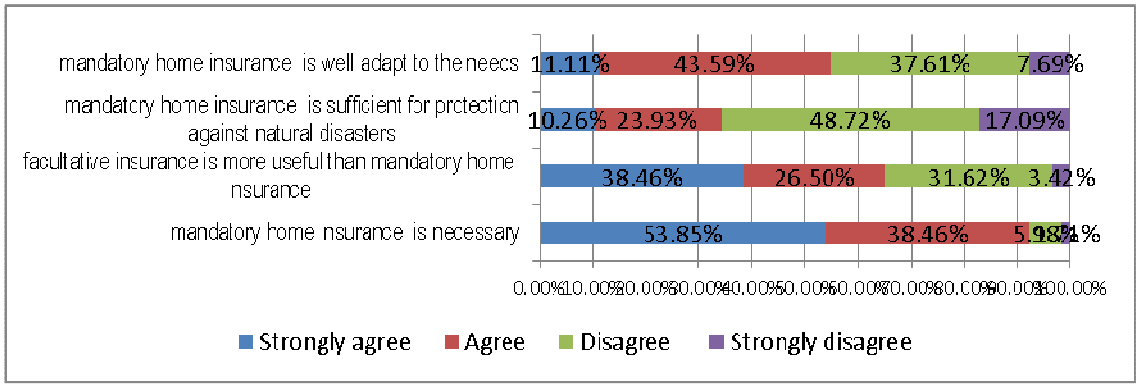


Fig. 2: Perception of the mandatory home insurance

The opinions regarding the way in which the specialists in insurance consider the insurance premium for mandatory home insurance indicate that it is perceived as being low (3.74). 41.03% of the subjects interviewed appreciate that the premium it is medium, 54.70% consider that the premium is cheap and 4.27% thinks that it is expensive.

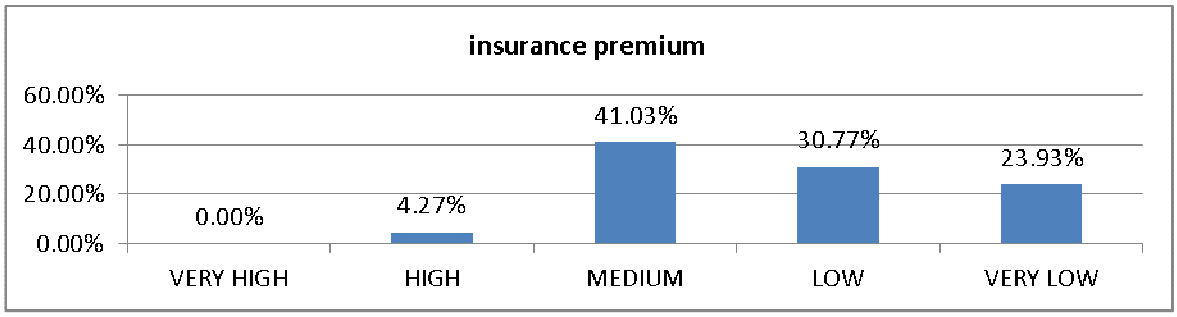

Fig. 3: Perception of the insurance premium for mandatory home insurance

The insured amount is considered medium (3.09). 61.54% of the respondents appreciate that the insured amount is covering the losses of natural catastrophes in a small measure, only 4.27% of respondents considering that the insured amount cover the losses in large measure. The answers indicate that the insured amount is not sufficient (2.22).

The general opinion regarding the collaboration between homeowners, public authority and insurance companies in the case of the mandatory home insurance is favorable (3.65).
In the opinion of insurance specialists, the reasons for which the homeowners close the mandatory home insurance (multiple choice question) are in the first place the need of protection against natural hazards (65.81%) and then the fear of penalties (55.56%).

In the opinion of insurance specialists, the reasons for which the homeowners do not close mandatory home insurance are: not understanding the necessity of the mandatory home insurance (67.52%), not having money (52.14%), not knowing the mandatory home insurance (45.30%) and the insurance premium is too high (11.97%).

Conclusions

The mandatory home insurance in Romania can be considered a measure taken to diminish the impact of the natural catastrophes on the budget of the Government. Mahul and Ghesquiere (2011) consider that governments in many parts of the world have been able to reduce the impact of disasters on their budget and to increase the resilience of their economy by promoting insurance penetration in the private sector.

There is a favourable perception of the mandatory home insurance among the insurers. The results of the survey indicate that in the opinion of insurers there is a need for mandatory home insurance, but there is a need as well for optional home insurance, which is considered more useful.

The direct research has revealed that the current risk solutions studied: the mandatory and optional home insurance are appropriate to the intensive risk, because there is a favorable perception regarding the financial instruments. Their scope and their mandate are appropriate to the risk reduction in the case of Romania, but there are several issues that can be improved and there is the necessity of a better long-term relation between the insurer and the insured because as Aerts and Botzen (2011) observed there are better incentives to reduce risk through undertaking damage mitigation measures by establishing a long-term relation between the policyholder and the insurer.

Abstract

In the world of excessive business competitiveness, almost every company tries to monitor its environment to exceed the competitors. Getting knowledge about competitors is the basic principal of what is called Competitive Intelligence (CI). Many applications of Competitive Intelligence can be used like Opinion Mining and Foresight studies and the process of obtaining such intelligence differs according to the company's needs. In this paper, we will present in more details the definitions of CI and a general process grouping the most used steps in conducting such study. In the end we will present some tools useful in CI.

Keywords: Competitive Intelligence, opinion mining, text mining, natural language processing.

Introduction

For a number of years, many firms have focused on the marketing principle of "knowing and satisfying customers at a profit". This focus has led these firms to consider new customer opportunities, modify channels of distribution, develop new products, and reorganize and restructure to achieve these objectives.

Most companies have informally monitored their competitors for some time. They know something about their competitors' management, markets and customers, products and services, facilities, technologies and finances.

As the business world gets more competitive, the informal information-gathering is no longer adequate for proactive companies. Because of the complexity of businesses and the uncertainty of the economic climate, these corporations are becoming far more sophisticated at inspecting the competition. They seek out more information, and spend more time and effort analyzing it. As these companies have discovered, an effective competitive intelligence program is absolutely necessary for success in today's—and tomorrow's—competitive environment.

In this paper, we will first start with an overview of Competitive Intelligence definitions. We will then focus in the second part on the steps of CI process. In the third part, we will see some applications of CI in the business world and the final part will present some CI tools.

1 Competitive Intelligence Definitions

We now live in a world driven by hyper-competition. Hyper-competition is where too many businesses are pursuing too little business; i.e. there is not enough demand to go around for all providers of goods and services. The knowledge base for managing in this hyper-competitive environment is called Competitive Intelligence. Competitive Intelligence is a process of giving you insights into what might happen in the near future. This process requires that we go from data to information to intelligence. The differences between data, information, and intelligence can be subtle, but very real (Evans, 2011):

- Data => Unconnected pieces of information: Nice to know, but so what!
- Information => Increased knowledge derived by understanding the relationships of data: Interesting, but how does it relate to what I do!
- Intelligence => Organizing the information to fully appreciate the implications and impact on the organization: Oh really, then we better do something!

Competitive Intelligence is one of the key factors for enterprise risk management and decision support. With the coming of the 21st century and the advent of Knowledge Economy, knowledge management and enterprise competitive intelligence have become two "Weapon" to respond to environmental changes, realize the organization innovation, and enhance the competitiveness. "Knowledge management" can condense enterprise's mutual recognition, and accomplish knowledge transformation, knowledge sharing and knowledge innovation within business to promoting enterprise power; "Competitive intelligence" can analyze and assess external environmental changes and keep a close watch on competitors' movements to make right competitive strategy, ultimately to maintain and develop competitiveness of enterprises. Knowledge management systems and competitive intelligence systems are two different levels of the concept, with different construction methods and steps, but their fusion is an inevitable trend (Tang & Li, 2010).

Competitive intelligence is frequently misunderstood as it's a sort of business espionage. The reason of this confusion is they both have common activities. Competitive intelligence means a "systematic process initiated by organizations in order to gather and analyze information about competitors and the general socio-political and economic environment of the firm". Espionage is unlawful and unethical while competitive intelligence is legal and associated with a detailed code of ethics (Colakoglu, 2011).

Fuld & Co. a high-profile CI consulting firm, takes an inclusive approach in defining the function of CI: "Competitive intelligence can mean many things to many people. A research scientist sees it as a heads-up on a competitor's new R&D initiatives. A salesperson considers it insight on how his or her company should bid against another firm in order to win a contract. A senior manager believes intelligence to be a long-term view on a marketplace and its rivals" (Fuld, 2014).

Competitive intelligence means a "systematic process initiated by organizations in order to gather and analyze information about competitors and the general socio-political and economic environment of the firm" (Colakoglu, 2011). According to Amarouche (2015) the CI is research and information processing in relation to the enterprise market in order that a company prepares its future actions based on these analyses.

The Strategic and Competitive Intelligence Professionals (SCIP), formerly the Society of Competitive Intelligence Professionals, is a global nonprofit membership organization for everyone involved in creating and managing business knowledge. According to SCIP definition, "Competitive intelligence is the process of monitoring the competitive environment and analyzing the findings in the context of internal issues, for the purpose of decision support".

Roberta Brody is an Associate Professor at Queens College, City University of New York and a member of Competitive Intelligence Foundation (CIF) wrote: "In answer to the frequently asked question (FAQ) "What is CI?", the Society of Competitive Intelligence Professionals (SCIP), gives the definition as "a necessary, ethical business discipline for decision making based on understanding the competitive environment" (SCIP, 2007a). The definition of competitive intelligence included as a parenthetical phrase in the summary section "About SCIP," currently posted on the SCIP website refers to competitive intelligence as "the legal and ethical collection and analysis of information regarding the capabilities, vulnerabilities, and intentions of business competitors" (SCIP, 2007b)" (Roberta Brody, 2008).

The main objectives of competitive intelligence in enterprises include the following (Bayandin & Kretov, 2012):

- Anticipation of changes in the market;
- Anticipation of the actions of competitors;
- Identification of new or potential competitors;
- The study of the successes and failures of competitors;
- The study of new technologies, products, and processes;
- The monitoring of changes in the political, legislative, and regulatory areas that affect a business;
- Start a new business;
- A clear view of an enterprise's own activities.

As a summary and based on these different definitions, we can state that competitive intelligence is a process makes to research, collect and analyze information in relation to the competitive market in order to know the strengths and weaknesses of competitors. So, the following part explains some processes of CI describing the most important steps of these processes.

2 Competitive Intelligence Process

Competitive intelligence is a process consisting of phases that are linked (Pellissier & Nenzhelele, 2013). The output of each phase is the input to the next phase. The overall output of the CI process is an input to the decision-making process. Among the competitive intelligence processes that exist in the literature, there is, first, the PCMAC (Plan and prioritize, Capture, Manage, Analyze and Communicate) model that consists of the following phases (Charlotte & Margareta, 2015):

- Plan and prioritize – The first step in this model where the work is planned, resources allocated and the key intelligence topics and questions are identified.
- Capture – where the information is collected.
- Manage – where the collected information is filtered, sorted and compiled.
- Analyze – where the analyses are done and the dots joined up.
- Communicate – where the result is disseminated to the target groups and archived for further use.

A Second process contains five steps (DAI, Y.,2013):

- Identification of CI needs – Identification of the key intelligence topics and the determination of the course the CI practitioner should take in completing the analysis.
- Acquisition of Competitive Information – Information collection of CI from different sources.
- Organization, Storage, and Retrieval –organize and store the information for CI.
- Analysis of Information – Brain of the CI system that transforms information into intelligence.
- Dissemination.

A third process (fig. 1) contains four steps (Amarouche et al., 2015) including time in order to make on-the-spot decision. The following part describes the most important steps of the CI process.

2.1 Identification of CI needs

This is the first stage of the intelligence cycle, which requires the identification of the key intelligence topics and the determination of the course the Competitive Intelligence practitioner should take in completing the analysis.

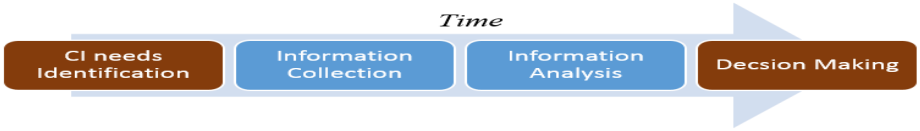

Fig. 1: Process of Competitive Intelligence (Amarouche et al., 2015)

Different names are given to this phase (Pellissier & Nenzhelele, 2013), such as 'obtaining CI request', 'intelligence needs and determine key intelligence topics', 'understanding the need', 'planning and direction', and 'defining CI demand'.

According to Botha and Boon (2008), this phase involves identification of intelligence needs of decision-makers and narrowing these intelligence needs down to key intelligence topics (KITs). The KITs are those topics identified as being of greatest significance to an organization's senior executives, providing purpose and direction for CI operations (Bose, 2008). In this phase, the CI director identifies and prioritizes both senior management and organizational key intelligence needs. Moreover, what the CI unit should research and to whom this intelligence should be delivered are determined in this phase.

According to Bouthillier And Shearer (Bouthillier & Shearer, Assessing Competitive Intelligence Software : A Guide to Evaluating CI Technology, 2003), the terminology "identification of CI needs" was chosen to represent the major information-related activity involved in this first step. This step is crucial for ensuring a relevant CI product.

2.2 Information Collection

The information research can start in the prioritized primary and secondary sources (Charlotte & Margareta, 2015). The primary information sources are the well-known phenomenon that much of the information needed in an organization is already there. It is, however, kept with different people and it is very difficult to get an overview of who knows what. One way to capture this tacit information is to participate in networks. Secondary information sources, covering explicit information, comprise not only various websites and databases, social media, newspapers, journals, reports and books but also the unstructured mass of e-mails, memos, forms, faxes... Previously, the problem that limits the functions of competitive intelligence is the lack of information sources, while nowadays with the emergence of web 2.0, the information about competitors can be accessed by the public on the web. E.g. the product opinions coming directly from customers are a source of information for CI. Also, discussions on different forums and blogs can provide crucial competitive intelligence when analyzed in proper perspective. Social media content can also contribute to competitive knowledge in a big way. Table 1 captures the different kinds of web resources along with the types of competitive intelligence they can provide (Dey et al., 2011).

Table 1 : Competitive Intelligence resources on the web

Type of competitive intelligence	Web resources
People events	News, company web-sites
Competitor strategies – Technology investment etc.	News, Discussion Forum, Blogs, patent search sites
Consumer sentiments	Review sites, social networking sites
Promotional events and pricing	Twitter, Facebook
Related real-world events	News, Twitter, Facebook

After the information has been collected from different sources, it must be organized and stored. This part of the CI process has typically been ignored in the CI literature, presumably because information is seen as having a very short life span (Bouthillier & Shearer, 2003). Now, the information is available to analyze. So, the next sub-section explains some techniques used in this part.

2.3 Information analysis

Called, by some, the brain of the CI system, analysis is the key process that transforms information into intelligence (Werther, 2001). Traditional data mining techniques are not aimed at dealing with unstructured and semi-structured materials written in natural languages. Thus, in the scope of CI, we need text mining (TM) and natural language processing (NLP) technologies to discover knowledge from textual information sources to gain competitive advantages. Technologies based on TM, NLP, web mining (WM) and visualization are presented in the analyses of several emergent CI software solutions (R. Bose, 2008). Many techniques can be used to conduct a good information analysis. Following are some of these techniques:

2.3.1 Natural Language Processing and Text Mining

Jurafsky and Martin (2000) state that the goal of NLP is to "get computers to perform useful tasks involving human language, tasks like enabling human-machine communication, improving human-human communication, or simply doing useful processing of text or speech". The ability to process natural language is the precondition for researching and developing the new generation of "intelligent computers." It is an essential technology to realize effective communication between a human and a computer that processes natural language at the semantic level. It is also a method for artificial intelligence (AI) to acquire general knowledge and logical ability.

The AI and NLP methods and technologies involved in the process of TM include: information retrieval (IR), information extraction (IE), WM, topic tracking, summarization, categorization, concept linkage, information visualization, and question answering (DAI, Y. ,2013).

2.3.2 Social Network Analysis

Social media have been adopted by many businesses. More and more companies are using social media tools such as Facebook and Twitter to provide various services and interact with customers. As a result, a large amount of user-generated content is freely available on social media sites. To increase competitive advantage and effectively assess the competitive environment of businesses, companies need to monitor and analyze not only the customer-generated content on their own social media sites, but also the textual information on their competitors' social media sites (He, Zha, Li, 2013).

Social network analysis is the study of social entities (actors) and their interactions and relationships. The interaction and relationships are represented as a graph, where each node represents an actor (user), and the edge between two nodes represents their relationship. Several link analysis algorithms have been proposed, that are applied on such graphs in order to identify and analyze the role, position, and influence of each user (Cagliero & Fiori, 2013).

2.3.3 Event Detection

Event detection (ED) is a subtask of information extraction (IE). ED focuses on identifying information about events, such as type, time, place, participants and date of the event. Examples of a business event appearing in a newspaper could be a company establishing a new factory or releasing a new product (DAI, Y., 2013). The advantage of ED is the ability to deal with unstructured data to capture the events

that have occurred in the environment, which can help in obtaining CI, to a certain extent, to monitor the business environment.

2.3.4 Opinion mining and sentiment analysis

Opinion mining (OM), also known as sentiment analysis (SA), refers to the process of identifying the opinions that a particular discourse expresses; it attempts to automatically measure human opinions from a text written in natural language. OM techniques have been recently used in applications such as extracting suggestions from consumers' product reviews, classifying consumers' positive and negative product reviews, tracking sentiment trends in online discussion boards, detecting Internet hot spots, tracking political opinions, determining consumers' dissatisfaction with online advertising campaigns, tracking emotions in emails, predicting stock market movements and differentiating between informative and emotional social media content (M. Mostafa, 2013). The application of opinion mining in many areas is also important for CI, e.g. companies to monitor the advertising or marketing activities of competitors or detect Competitors' products news.

In this part, we have discussed the main steps of the general process of CI. We also highlighted some techniques used in Information Analysis step. This will lead us to a very large number of applications of CI in different domains like Foresight that contains trends analysis and weak signals detection. In the next part, we will present some of these applications.

3 Competitive Intelligence Applications

There are many areas where competitive intelligence might be applied including Research& Development (R&D) management. Competitive technical intelligence (CTI) and strategic technological foresight (STF) are two good examples applied by a foresight program that recently studied Canada's foresight capacity (Colakoglu, 2011).

CTI is competitive intelligence within the R&D arena and is defined as "business sensitive information on external scientific or technological threats, opportunities, or developments that have the potential to affect a company's competitive situation" (Calof & Smith, 2010). It is also defined as Competitive Intelligence with a strong emphasis on science and technology and their impact on research and development activities. CTI is clearly focused mainly on supporting competitive advantages within business firms and industrial organizations such as industry associations. (Dou & Manullang, 2004).

On the other hand, STF has mainly evolved with the cooperative practices of the US military technology planning environment (e.g. Rand Corporation), global oil and resource processing business roots (Royal Dutch Shell Group Planning, and The Global Business Network) and the Japanese and German government's Delphi work of the last 30 years. STF is defined as "a set of strategic tools that support government and industry decisions with adequate lead time for societal preparation and" strategic response". STF can also be both a source of CTI and a means for its application. In business, new and emerging technologies pose constant risks of rapid eclipse – known as disruptive technologies (Calof & Smith, 2010).

Other applications of CI can be cited like product opinions (Amarouche & al., 2015). So, the company may be interested in gathering and analyzing the sentiments and opinions of costumers about a product or a service of its competitors in order to track the market environment. As it says, tracking the market can be very helpful to be ahead of the newest product lunched for example and this will help the company to improve its own products. The last example is the foresight, and this is an important need that many companies are focused on and also contains many sub areas like Trends analysis (Kevin et al., 2008) and Weak Signals detection (El Akrouchi & al., 2015).

Now that we have seen some applications in CI, we will present in the next part some tools used to conduct a full process of Competitive Intelligence.

4 Existing Competitive Intelligence Tools

As business decision makers are getting more interested in CI, many academic researchers have developed new text-capable solutions and algorithms, and in parallel, several software companies have developed products to help analyze textual data. For example, Cheng (2010) develop CTMiner using data mining to mine time interval-based patterns (Cheng et al., 2010). IR and IE are employed to detect topics and events based on a timeline (Y. Jiang, 2011).

In this part, we will talk about existing competitive intelligence tools that are available to companies to know more about their competitors. The following tools have different capabilities like semantic analysis, natural language processing, statistical analysis…There are various software tools in the market that claim to help the collection and analysis of CI. Table 2 summarizes the CI software that are the most relevant to the research reported in the thesis.

Table 2: Summary of CI software that utilize TM technologies (DAI, Y., 2013)

Tool name	Vendor	Type of tool	CI methods	Data sources
BusinessObjects	SAP	TM, OM, WM	Enterprise performance management, information management	UT
Enterprise Miner	SAS	DM, WM	Modeling and assessment, statistical analysis	SD
Coldfire Innovator	Coldfire	TM, WM	Product lifecycle management, enterprise resource planning	UT
LUXID®	TEMIS	TM, OM, WM	Competitor analysis, strategy management, weak signals	SD, UT
OneCalais	ClearForest	DM, TM, WM	Knowledge management	SD, UT
RapidMiner	Rapid-I	DM, TM, OM, WM	Enterprise performance management, customer monitoring	SD, UT
SPSS	IBM	DM, TM, OM, WM	Customer analysis, environment monitoring	SD, UT
STRATEGY!	Strategy Software, Inc.	TM, WM, data visualization	Benchmarking, SWOT analysis, competitor response profile	SD, UT
Text Analytics	SAS	TM, OM, WM	Customer monitoring	UT

Key: DM = data mining, TM = text mining, OM = opinion mining, WM = web mining, SD = structured data, UT = unstructured text

As illustrated in Table 2, all the evaluated text-capable CI software apply TM and NLP technologies. Only RapidMiner and SPSS use DM, TM, and NLP technologies, including OM and WM.

The benefits of BusinessObjects are the extraction and federated search, but it requires an input of specific categories for practical use in particular industries (Y. Dai, 2011 ,2013). Enterprise Miner can

mine document sets and cluster the documents into common themes based upon document content. Goldfire Innovator has a sophisticated semantic analysis module, but it requires in-house training and has a high cost (Y. Dai, 2011). LUXID® offers powerful TM solutions to help users drill down the full text to discover the most relevant answers, but it has limited visualization options and high costs (Y. Y. Yang, 2008; DAI, Y. ,2013). RapidMiner supplies powerful TM and NLP technology to analyze text by customizing the analyzing process, but training and background knowledge on TM technology is required to use the system efficiently (DAI, Y. ,2013). The strength of Text Analytics is the extraction module, but it needs a significant investment of money and training (Y. Y. Yang, 2008).

Other competitive intelligence tools are used. We can find:

- **Cipher Systems' Knowledge.Works**[1] **-** Cipher's award-winning competitive intelligence software application, Knowledge.Works can be customized to facilitate everything from concentrated competitive intelligence efforts to everyday decision-making tasks. Taking advantage of the existing database infrastructure, (Lotus Notes, MS SQL Server or Oracle), Knowledge.Works satisfies most intelligence process and application requirements.
- **Intellicomp CIS (Competitive Intelligence System) Software**[2] **-** is an information management system designed to hold a wide spectrum of strategic and tactical information about the competitors, plans and programs for dealing with the competition.
- **AMI**[3] **-** AMI SCI is a strategic and competitive intelligence software solution. It is specifically designed to capitalise on the value of information held within large volumes of unstructured data.
- **Acquisition and Competitor Intelligence System (ACIS)**[4] **-** is an application solution for growth-related business processes. The ACIS intelligent portal integrates internal and external information to create new insights about opportunities and threats, and supports acting on them.
- **AdGooroo Search Engine Advertising Intelligence**[5] **-** is the leading provider of advertising intelligence to search engine marketers. Its proprietary technology tracks all search advertising activity in any given industry, empowering sophisticated agencies and advertisers with competitors' keywords, ad copy, campaign statistics, daily alerts, and other information needed to generate the highest possible return on advertising investment.
- **ClearCI**[6] **–** ClearCI automates four activities that are conducted manually in an inconsistent, ineffective and unstructured format: Research, Monitoring, Organizing and Sharing. ClearCI empowers today's knowledge worker to become more efficient.
- **Attaain, Inc: AttaainCI**[7] **-** is an award-winning web-based solution for business development, sales, marketing and competitive intelligence research, analysis and tracking. The system is used by companies in a wide range of industries to identify and track key sales prospects, customer growth opportunities, competitor activities, strategic partner prospects, industry developments and more, across single or multiple lines of business.

In this part, we exhibited and categorized some tools existing in the market that help conducting efficient competitive intelligence analysis.

5 Conclusion

Competitiveness exists in every business environment, a thing that incites companies to look for new and efficient ways to lead the market and to know more about competitors. These techniques and ways are grouped in a very large field which is called Competitive Intelligence. It creates many research leads using a large number of techniques and approaches.

In this paper, a general overview of definitions of Competitive intelligence was presented. We exhibited some processes generally used to conduct this study. We presented, then, a detailed definition for each step of the process and the techniques used. We mentioned some applications of CI and finally an overview of the tools existed useful for this area.

Abstract

In SMEs from ITC sector, where management often lies in the hands of the entrepreneur, there can be a lack of the resources and competences necessary to generate important changes and innovation. Literature review considers innovation to be the main determinant of a firm's capacity to generate added value. We selected a sample of 79 family-controlled SMEs and gathered managerial information about them. We collected data on the change and innovation of these family-owned firms by interviewing their entrepreneurs or top managers and by through regression analysis of the data collected we demonstrate the importance of managerial teams. This paper presents only a theoretical approach regarding team management issues developed in our qualitative research.

Keywords: entrepreneurship, change, family firms

Theoretical Background

Most studies which conclude that the performance of family firms is worse than that of their non-family counterparts (Morck et al., 2000) suggest that the “family's desire for stability and risk aversion keep the company from pursuing strategies that might otherwise improve performance, but would also threaten the family's continued control”. Furthermore, this risk aversion can limit the firm's ability to grow and innovate (Cho et al., 2005). Family firms have also been found to pursue cautious investment policies that likewise tend to inhibit growth (Mustakallio et. al., 2002).

Conversely, research suggesting that family firm performance is superior to that of other firms often uses the argument that families are better stewards of firm resources because of an overall aversion to managerial opportunism to explain this result (Ceptureanu EG, 2015a). Recent research seems to provide compelling evidence of superior family firm performance (Miller et al., 2006). The negative and positive effects, of family ownership-management upon SME ability to develop change and innovation, will be described separately as the dark and bright sides of family management in SMEs (Ceptureanu EG, 2015b). Despite this, most studies have focused on explaining aspects of financial performance, while few have examined how the broader management structure of the firm affects change and innovation (Pettigrew, 1992; Ceptureanu EG, 2015c). In an SME context, the use of performance as a dependent variable is problematic due to the multitude of goals that usually prevail in such firms (Wiklund, 1998). Concerns for employee well-being and/or the welfare of the owner-family may be of great importance to small business managers (Wiklund et al, 2003), rendering other dependent variables, such as change and innovation, appropriate.

On the other hand, change and innovation typically generate risks. Concentrated nature of ownership puts closely held firms at a disadvantage in terms of risk bearing and promotes inertia (Schulze et al, 2002).

Moreover, in the family firm, the blending of family and business matters in decision-making may promote inertia, for instance when a CEO postpones necessary business decisions, such as a generational succession, because of concerns about family welfare (Schulze et al., 2002). There is also a current in the family firm literature that depicts these firms as conservative and resistant to change (Aronoff et al., 1997), introvert (Poutziouris et al, 2004), and paralyzed by internal family conflict (Barach, 1984).

The concentration of ownership among the firm's top management can lead to risk aversion and a lack of willingness to engage in change activities such as product innovation or entering into new markets (George et al, 2005). It also means that the entrepreneurs, given that they are family members, will be subjected to less pressure from outside investors and other monitors who demand accountability, transparency and renewal, things which might give rise to a defensive attitude that may harm efficiency (Carney, 2005).

With respect to the theory of the firm, the Stewardship theory (Davis et al, 1997) offers a different and complementary perspective on family purposes and behaviour. It posits that managers and entrepreneurs are driven by more than economic private interest, and often act altruistically for the benefit of the entire organization and its stakeholders. The belief is that stewards are motivated by higher level needs they identify with the organization, embrace its objectives, and act for its collective good.

Another important feature of family firms is that the controlling shareholders normally aim at keeping their investment in the long term. Indeed founding families "are a unique class of investors. The combination of undiversified family holdings, the desire to pass the firm onto subsequent generations, and concerns over family and firm reputation suggest that family shareholders are more likely than other shareholders to value firm survival over strict adherence to wealth maximization"' (Anderson et al, 2003). From a stewardship perspective, the orientation toward the firm's long-term survival is seen as a motivation to manage capital carefully and invest in long-lasting assets, like reputation and social capital (Miller et al, 2006a), for the benefit of all stakeholders.

To increase returns over what could be a lengthy career, family CEOs may make what are quintessentially farsighted investments, such as those in research and development, training, and state-of the-art infrastructure. Indeed, some evidence reveals that family firms do outspend non-family firms peers in R&D (Miller et al., 2006b) and in capital investments in plant, equipment, and even information technology (Kang, 2000). Due to these stewardship concerns, large investments in the future and refusal to be distracted by short-term expedients, family-managed firm will have a better chance of developing distinctive core capabilities (Munteanu et al, 2015a). Boards of directors perform a service task and are supposed to bring different types of resources to the firm (Huse 2005). These resources, which also include knowledge and relationships with third parties, may become indispensable for the making of change when the firm's environment changes significantly (Gales et al., 1994, Ceptureanu SI, 2014).

With regards the firm's innovation processes, Moran et al. (1996) state that, in order to create new or better products and services, firms need to exchange and combine new resources, or find new ways to do so with existing ones. Innovation requires diverse resource inputs and combinative capacities (Kogut and Zander, 1992). Thus, giving access to the board to individuals with knowledge and experience or combinative capacities that are different from those of the family owner-manager, may be associated with innovation, which may serve as an indicator for value creation (Tsai and Ghoshal, 1998, Nicolescu et al, 2009; Ceptureanu SI, 2015a). A board, which does not limit itself to controlling, but rather assists, the management might reinforce the initiatives of change and innovation undertaken by the family owner-manager and/or may minimize or oppose tendencies towards stagnation, immobility and poor innovation (Ceptureanu SI et al, 2015a).

According to the upper echelon theoretical perspective (Hambrick et al., 1984), the management team may also help increase the firm's potential for change and innovation (Ceptureanu EG, 2015d). This perspective purports that firm performance is a "reflection" of the characteristics and actions of the firm's central managerial team, known as the management team. In this work, it is argued, in accordance with past research, that the human capital of this team is an important element in success (Thakur, 1999).

Higher echelon research generally focuses on the entire group of the firm's top executives as the appropriate level of analysis, and, thus, implicitly assumes an even distribution of power within the elite echelon of corporate actors (Dalton et al., 2005). However, there is research which supports the argument that group characteristics are relatively less important than the characteristics of the leader (Cannella et al., 2005). This particularly applies to family-controlled firms where a CEO who belongs to the main owner family exerts a strong leadership influence on corporate decisions and outcomes (Munteanu et al., 2015b).

Romanian small- and medium-sized companies often have a single administrator or a small sized board which nominates the managing director from within (Ceptureanu SI et al, 2015b) use the title chief executive officer to indicate this single administrator or managing director. The CEO is the leader of the management team (Wu et al, 2005) and dominates the distribution of responsibilities and tasks within the team itself (Haleblian et al., 1993).

In SMEs which are also family firms, board and top management often overlap, with the same people, or people from the same family, involved at all levels (Mustakallio et al, 2002; Nordqvist et al., 2002). Therefore, management research regarding small or medium-sized family firms investigates how ownership, board and management are interrelated in creating key organizational outcomes such as change and innovation (Ceptureanu EG et al, 2014). In this work, the CEO is a family member who controls the company and at least one other family member is present in the management team. However, the size of either the board or the management team may grow as a result of individuals from outside the controlling family becoming involved.

A board of directors may make an important contribution to the firm's strategy with regards, generally, the processes through which the firm makes its most important decisions. Indeed, boards participate in various phases of decision making through interacting with management team (Forbes et al., 1999). Previous to this, the international literature had shown the important influence of board insiders and outsiders in the choice of the firm's innovation strategies. The board has been described as the "apex of the firm's decision control system" (Fama et al., 1983). Family SMES, however, are closely held and owner-managed and thus owners have direct and detailed insights into internal processes of the firm (Cowling, 2003). In such closely held firms the role of the board is different, because the risk of opportunistic behaviour by management is lower (or zero). The board can therefore focus less on control and more on service activities, such as on stewardship and development. As a result, there is less need for the board's control function (Brunninge et al., 2004), while a vital function of the board is to perform service tasks. Over the last two decades, researchers have enhanced our understanding of the board's tasks from different perspectives (Ceptureanu EG et al, 2012). Fama and Jensen have pointed out that, according to agency theory, the board should perform ratifying, controlling and evaluating strategies to fulfil its function as "the apex of the firm's decision control system" (Fama and Jensen, 1983). In an early review of boards of directors, studies applying resource dependency theory show that directors' involvement in the strategic arena usually takes the form of initiating analysis and suggesting alternatives (Zahra and Pearce, 1989). Based on a practical view of board strategic involvement, other researchers have specified implementing strategies as one critical part of this involvement (Huse, 2005). In short, board strategic tasks cover a set of activities that may range from initiating strategies to implementing them.

Managerial Team in SMEs

The ability to introduce innovation in family firms is influenced by phenomena which typically affect this type of firm and are related to the management team. Carney (2005) theorises that the tendency to restrict the top management team to family insiders is one of the ways in which these firms exhibit their natural parsimonious propensities. There is a strong negative relationship between such propensities and the capacity for innovation, since parsimonious propensities may encourage an efficient operational environment which roots out some of those slack resources that Nohria et al. (1996) describe as necessary for successful experimentation and innovation (Gedajlovic et al., 2010).

Ensley et al. (2005) suggest that management teams with many members from the same family should mean more shared consensus in the management team as a result of altruism, loyalty and commitment. Moreover, the fact that a management team quickly achieves a greater consensus regarding a firm's strategic direction is not always beneficial to that firm's innovation processes. Indeed, Gedajlovic et al. (2010) note that in firms where family members dominate the management team, such a consensus is soon arrived at, but that such dominant leadership may reduce constructive dialogue and the screening of novel ideas.

Cohen and Levinthal (1990) define the absorptive capacity construct as the capacity of a firm to value, assimilate and apply, for commercial ends, knowledge from external sources (Ceptureanu SI, 2015b). Based on previous studies such as Allen (1984), they hold that absorptive capacity is a by-product of an organization's Research and Development (R&D) efforts. However, the passage from knowledge absorption to its economic use is not always guaranteed (Ceptureanu SI, 2015c). Greater effort in R&D means greater capacity to generate within the organization and interpret and understand the knowledge of others, but Davenport and Prusak (1998) note that absorbed knowledge, whether from an individual or an organization, may remain unused for diverse organizational reasons. This argument is highly relevant in this paper given that it is directly linked to the functions performed by management teams in SMEs (Ceptureanu SI, 2015d). Indeed, small size and flexible organizational structures intensify its involvement in all of the firm's activities. For example, specialized departments for marketing and product development are less common in SMEs (Cowling, 2003) and, if they exist, their decisions are heavily influenced by top management.

Non-family member involvement in management teams increases diversity and the breadth of the organization's knowledge base (2014; Gedajlovic et al., 2010), so helping the processes by which knowledge absorbed from external sources can be utilised within the firm and incorporated into its own product portfolio. The resource-based view "perceives the firm as a unique bundle of idiosyncratic resources and capabilities where the primary task of management is to maximize value through the optimal deployment of existing resources and capabilities, while developing the firm's resource base for the future" (Grant, 1996). In dynamic markets the dynamic capabilities by which firm managers "integrate, build, and reconfigure internal and external competencies to address rapidly changing environments" (Teece et al, 1997) become the source of sustained competitive advantage (Ceptureanu EG, 2015e). The manipulation of knowledge resources, in particular, is especially critical in such markets (Grant, 1996, Ceptureanu SI, 2014).' Research on the dynamic capabilities of the firm (Raff, 2000) suggests that dynamic capabilities are embedded in organizational processes and are directed toward enabling organizational change and evolution (Zott, 2003). These capabilities enable the firm to reconfigure its resource base and adapt to changing market conditions in order to achieve a competitive advantage.

The effect of team management characteristics on change is likely to be particularly strong in SMEs because flexible organizational structures intensify management team involvement in all activities of the firm. When non-family members are involved with the management team, this leads to an increase in the

diversity of the organization's knowledge base (Ceptureanu SI, 2015a). Therefore, larger management teams are likely to have more resources and competences available to them in decision-making. Moreover, team management members are unlikely to have the same tasks, so adding to diversity. By increasing cognitive diversity, a larger and functionally more varied group may increase creativity in decision-making and point to new alternatives for the firm's future development (Forbes et al., 1999). In closely held firms, a larger team management with more non-owner top managers may partly counteract the dominant influence that the owner-managers otherwise has on strategic direction. Being one of several management team members, the individual member may feel more confident about suggesting alternative strategic ideas and advocating change. Hence, a larger team management should increase willingness for change as well as the number of available options for carrying out change.

Conclusions

Small- and medium-sized family firms have tendencies which may inhibit change and innovation. The inclinations of family firms may promote an efficient operating context which hinders the forming of all those conditions that Nohria et al. (1996) describe as necessary for successful experimentation and innovation. Family firms have also been found to pursue cautious investment policies that likewise tend to inhibit growth (Mustakallio et al., 2002). Furthermore, this risk aversion can limit the firm's ability to grow and innovate (Cho et al., 2005) and might lead to “reluctance to change” (Denis et al, 1997) and a general “conservativeness” (Sharma et al., 1997).

Particularly in SMEs, there can be a lack of resources and competences to generate change. The results indicate that it is possible to facilitate change by introducing an integrated management system who can increase general competence of the company and its employees. The presence of outside directors on the board makes change more likely to happen. The additional managers can contribute to change by increasing cognitive diversity (Forbes et al, 1999), linking the company to important stakeholders (Huse, 2000) and increasing the legitimacy of the organization (Johannisson et al., 2000).

The results do not support the hypothesis that the including of outsiders on the board leads to improvement in the family SME's innovation capacity. In order to interpret the latter result correctly, it should be remembered that board insiders are those who work for the company on a daily basis, whether or not they are a part of the main owner family. What is said in the literature about innovation requiring a high degree of intra-firm integration should also be born in mind: a firm involved in innovation brings more insiders on to the board in an attempt to integrate the functional activities of the firm around its strategy (Hill et al., 1988). By way of contrast, a firm which has diversified into many different fields brings outsiders on to the board for their expertise (Hill et al., 1988), either of the different areas the firm is active in, or in pursuing a diversification strategy. Board members might be selected by family owner-managers of SME on the basis of requirements. Given that, by virtue of their selection, insiders are likely to prefer innovation and outsider’s diversification. In particular, greater effort in R&D means greater capacity to generate knowledge within the organization and interpret and understand the knowledge of others (Ceptureanu SI, 2014). However, the tendency of family owned firms to restrict the top management team to family members may inhibit the development of absorptive capacity, and reduce access to outside sources of information that are needed to calibrate and refine the complex systems which often constitute the base for important innovation. Our study is not without its limitations. We opt for a sample that contains SMEs from the same sector- ITC(Ceptureanu EG et al, 2014). In this sector, change and innovation are very important aspects in a firm's survival. The advantage of analysing data from firms belonging to the same sector is the homogeneity that characterizes the examples studied. We need to understand the fact that change and innovation are complex phenomena and that management mechanisms only represent a limited part of the variables affecting change and innovation in a small company. On the other hand, the data for this study were gathered only in ITC sector of Romanian

economy. Therefore, special attention should give when generalizing about our discoveries both with regards other sectors and cultures.

Abstract

Recent discussion of the analysis of poverty at old age draws attention to the limitations of currently dominant approaches. Measuring the incidence of poverty at old age is an important first step in understanding it, but measurement alone does not explain the causes of poverty. This paper draws the discussions on causes of elderly poverty across the countries and develops an analytic framework of poverty at old age. Research framework and propositions are suggested to guide the future research in this area.

Keywords: retirement, elderly poverty, Malaysia

I. Introduction

Many countries have experienced aging phenomenon. However, it seems to be a shocking trend for the world population as this issue would somehow affect the development process of the country. According to statistics from Malaysia's Department of Statistics, the average life expectancy in Malaysia has increased to 75 years but most employees stop working at the age of 55 compare to Sweden where retirement age is 67 (Department of Statistics Malaysia, 2010). Malaysia is predicted to have 15% of elderly populations by 2030 and elderly Malaysian have experienced alarming rate of poverty at 22.7 per cent (United Nation ESCAP Report, 2008). Most Malaysian does not have adequate saving when they get retired. Survey reported that average saving of people at the age of 54 years is $ 3,9750. The required amount for them to survive is $4,7500 (EPF annual report, 2009).

Whereas 50% of retirees finished pension fund within 5 years, 70% of them finished their saving within 10 years, and 14% of them finished it within 3 years. These facts are alarming especially those who are still thinking that to rely fully on their pension fund saving for the postretirement income. Rapid increase in the aged population, together with the longer life expectancy reflect that well planned personal financial planning turns out to be of utmost important (Mohidin et. al., 2013). According to Kim (2003), most of the people were not afraid to retire but they are not well prepared for retirement due to lack of money. More than 90% of Malaysians do not prepare for retirement and they do not take into account of inflation rates and rising medical costs (Lai et al, 2009).

II. Financial Support for Elderly living in Malaysia

Malaysia is a Southeast Asian nation and constitutes of two districts (Peninsular Malaysia and East Malaysia). The Malays, Chinese, and Indians are the main ethnic groups in Peninsular Malaysia, whereas indigenous people are concentrated in East Malaysia. Malaysian citizens consist of around 55% Malays, 24% Chinese, 7% Indians, 13% Indigenous people, and 1% of other ethnicity (Department of Statics Malaysia, 2010) The Government has always maintained that it is the responsibilities of children to provide care and support for their aging parents (Caraher, 2003 & Chan, 2005). Traditionally, it has been the norm and cultural practice of all ethnic groups for children to repay their parents (Yaacob, 2003). However, Malaysia has undergone rapid demographic transition, with continuing decline in fertility and increasing life expectancy over several decades. Since independence from British rule in 1957, the total fertility rate has declined from 6.1 per woman to 2.1 in 2010 (Departmental Statics of Malaysia, 2014). The increasing number of older persons with diminishing family size will put more stress on traditional family support systems. Previous findings in Malaysia revealed that older Malaysians, especially those living in rural areas, largely depend on financial support from their children (Tengku Aizan, H and Jariah, M, 2010). However, family support for the elderly may be eroding due to social-demographic changes such as the trend towards delayed and non-marriage, shrinking family size, out migration of the children, increased female labor force participation, and living in condominium (National Population and Family Development Board Malaysia, 2004).

Pertaining to retirement financial planning, most working Malaysians are depending on monthly contribution to employee pensions fund (EPF). It has an average contribution rate of around 23% (i.e. employer 12% and employee - 11%) of their gross salary every month to their retirement savings with EPF (Ong and Lee, 2001). Malaysia's EPF was established in 1951 and it is the oldest provident fund (PF) scheme in the world (Thillainathan, 2004). Compared to other East Asian countries, Malaysia is in higher rank with respect to the overall contribution rate to pension fund however with respect to retirement age, it has only recently legislated to be increased to 60 (refer to the table 1). Nowadays most Malaysian do not have enough saving when they get retired and they used up their pension fund within few years. Table 1 shows an overview of contribution rates and retirement ages for selected countries in Asia and some other regions. Refer to table 1, it shows that Malaysia's pensions fund has higher contribution rate of total 23% to pensions fund compare to United States which has 12.4%, even Japan as 23% and U.K as 23.8%, however Malaysia retirees still do not have enough saving. Statistics further shows that Malaysia's per capia income of $ 10,432, which is far lower than United States with amount of $ 51,749, United Kingdom with amount of $ 39,093 and Japan with amount of $ 46,720. Whereas, Singapore which is closer neighborhood of Malaysia, it has higher income capital $ 51,709 with highest pension contribution rate with total of 38% (Holzmann, 2015).

Malaysian elderly are living longer that increase the percentage of the total population. Taking into consideration of normal retirement age as approximately 55 years, there is an urgent need to establish an adequate system that cover sufficient saving when they get tired. This begs the questions of:

- What are the reasons behind most Malaysian ends up with poverty at old age?
- What direction they should plan for the future retirement so then they can live comfortably at old age?

Therefore, the purpose of the study is to explore the causes of poverty at old age and also to recommend the action to reduce the poverty at old age.

III. Causes of Poverty across the World

In many non-western countries, such as Malaysia, there is considerable debate over how much government versus family support should be provided for the care of the older population. In United States where government provided substantial transfers to the elderly through social security and medicare, some non-western countries are trying to reinforce family support-networks (Da Vanzo, 1994,). The lack of comprehensive social security system in most developing countries including Malaysia increases vulnerability of the elderly to poverty especially among older women and the self-employed (Caraher, 2003). Meanwhile, limited financial resources, coupled with inability to manage financial resource, can lead to financial problems (Suwanrada, 2009). Today's older Malaysians are unguarded to poverty due to forced retirement, lack of saving during younger years, limited social security coverage, and coupled with changing family structure and lifestyles, (Masud and Haron, 2014). Increased cost of living becomes another factor for the need to have good financial practices. Good financial practices during younger years can be a factor to ensure financial security in old age since one of the recommended financial goals is savings for old age (Garmen and Fougue, 2004).

Table 1: Contribution rate and retirement age of selected countries

Country	Per capia Income 2012 (US$)	Employee Contribution Rate (%)	Employer Contribution Rate (%)	Total Contribution Rate (%)	Statutory Retirement Age
East Asia					
China	6091	8.0	20.0	28.0	50/60

Poverty among the elderly has been a global concern, as stipulated in the Madrid International Plan of Action on Aging 2002 (United Nation, 2002). People in sub-Saharan Africa, are among the poorest in the world, not only in terms of real income but also access to social services. Traditionally, the African social structure was established around the family and even the extended family network was closed together. This network assure against all disabilities of old age and other shortcomings. A general assessment of poverty in old age at provincial level reveals that the majority of the aged are poor due to unemployment/retrenchment (Madzingira, 1997). In the later research, Carter and May (2001) further clarify that functional illiteracy is higher among the chronically poor, and other risk-

reducing measures such as insurance and savings as important issues for poverty reduction. Issues for further analysis include the impact of unemployment and the prospect of early involuntary retirement must take into consideration.

Where as in United Kingdom, aged population is projected to increase rapidly and a significant minority of people of pensionable age fully dependent on state-based financial assistance. Besides due to absence of money, causes of poverty are; intergenerational worklessness and economic dependency, family breakdown, serious personal debt, educational failure, and addiction to drugs and alcohol (McKee, 2009). In the case of Latin American and the Caribbean, the incidence of poverty among older persons is not only based on income. It also depends on factors such as health, education, and labor market opportunities. Thus, poverty is certainly a multidimensional issue. Aging Americans like other age groups are feeling the effect of challenges at old age poverty. Currently, 3.4 million senior ages 65 and older live below the poverty line and retirement income adequacy will decline due to insufficient amount of social security benefits and less certain income from employer pensions (Munnell and Soto, 2005). Although government has increased the social security benefits to reduce the elderly poverty, high medical cost can reduce the income available to meet the other needs (Cawthorne, 2008). Thus, American Government has introduced the ObamaCare program in 2010 to give more Americans access to affordable and quality health insurance. This program expands the quality, affordability, and availability of private and public health insurance.

Causes of poverty in developed countries like Canada are due to lack of sufficient income and resources to live a full life. Some analysts view poverty as the outcome of personal decisions such as dropping out of school, having a child at early age, becoming addicts to drugs/alcohol or refusing to relocate the employment. Other analysts argue that poverty is a product of government programs that are not well structured. The middle ground is both individual and social responsibilities coexist. Echenberg (2009) identified four ways to reduce the elderly poverty by having income from investment at early age, income from work, income from government transfers such as provide incentives to participate in labor market, and support particular behavior or activities and non-monetary benefits such as affordable child care, social housing, and recyclable affordable used clothing. Canadian federal and provincial financial support programs provide the financial support to nearly all provinces (Ruggeri et.al,1994) and also ensured that there should not be any individual falls below the threshold (Sarlo, 2001). Feedbacks from retirees conclude that retiring Canadians have adequate financial resources, with the exception of those who retired involuntarily as a result of poor health (Alan et al., 2007). Unlike the U.S. system, which relies on the earnings-related pension component, Canada's system offers a guaranteed income in the form of Old Age Security (OAS), regardless of past participation in the labour force. Thus, Canada Government has well designed and effective old age fund for its citizen (The Conference Board of Canada, 2016). Surprisingly, Australia has the higher rate of elderly poverty, and nearly 40 per cent of Australian seniors live in relative poverty. An OECD (2009) report notes that increase in elderly poverty in Australia is due to inefficient income-support payment program.

In South Korea, families and close relatives provided majority of financial support for elderly. The government took advantage of this and did not prepare any extra measures to provide the elderly with pensions (Cook and Kim, 2010). The public pension scheme was only introduced in 1988, and retirees do not have accumulate pension entitlements in the new system when they retirees in the mid-2000s. With modernization, tensions and gaps between generations will diminish the elderly roles in society and could lead to less responsibility for the younger generations to support elderly. Thus, the root cause that contributes to the higher rate of elderly poverty in Korea is due to late preparation for proper pensions system for the citizens, secondly is due to the lack of support from families, thirdly elderly do not save enough to sufficiently support themselves and finally is they have provided extensive support for their children (Lee, 2014).

Southeast Asian countries are sometimes grouped with East Asian "developmental stages" (Japan,) which maintained a low level of spending on welfare but with social policies bring used in the overall pursuit of economic development (Kwon, 2005). The reason was due to initial focus on contributory social insurance programs, household saving, and universal access to education. The policies of these

countries have also been described as productivity in emphasizing investment in education and public health as underpinnings of economic development (Wood and Gough, 2006). Singapore is expected to experience rapid aging of its population in the next two decades. Therefore, old-age income security is increasingly becoming an important economic, social, and political issue. Citizen concerns are growing across a range of social issues, including: relative poverty; access, equity and affordability in health care; and retirement income provision. Both in Singapore and Malaysia, social protection relies primarily on personal savings and family support networks and whole government support is channeled towards public provisions of health and education services (Cook and Pincus, 2014)

Many people regard 'absolute poverty' as no longer existent in a Western European context. The EU Member States agreed on using poverty indicators, which are one-dimensional (monetary) and relative (based on a threshold defined in relation to the distribution of income within each country) (Eurostat, 2005). A poverty measure commonly used within the EU is to describe individuals as poor whose net equivalence income is less than 60 per cent of the median income in a given population (BMGS, 2005). Since the late 1980s/early 1990s researchers and policymakers alike have increasingly acknowledged the multi-dimensional character of poverty. The key question for European, national, regional, and local policymakers concerned with the alleviation of poverty in old age is how to reduce the risk of poverty in the long run. Research evidence points to the crucial importance of education – the higher the level of education and, thus, the socio-economic status – of any individual (young or old); the less likely is s/he to be affected by poverty. These are the strongest determinants of health and quality of life in old age (Marmot & Wilkinson 1999).

The basic ingredients for a review of causes of poverty are much similar across countries in the region: low income, unemployment, no education/low level of education, no proper financial planning, spends too much on the children, lack of support from children, inadequate pension program, and expensive health care.

IV) Literature review on root causes of elderly poverty

One route for investigating the causes of poverty is to examine the dimensions highlighted by poor people. Some of the reasons could be due to low income and assets to attain basic necessities. Other relevant variables as education, health, housing, water, sanitation, and labor market opportunities also should not be ignored. Global Age Watch Index (2015) provides a good working framework to review the measures of vulnerability for older people. The framework identifies four domains of well being for older persons. These are 1) financial security, using indicators on the pension income beneficiaries ratio, older people's incomes or consumption relative to the rest of the society, and poverty risk among older people, 2) health status, using healthy life expectancy at 60, and psychological well-being as indicators of physical health and mental well-being, 3) Employment and education among older people as a proxy for the coping attributes of older people, given that lacking these attributes makes them more vulnerable; and 4) Enabling environments, using indicators pertinent to enabling age friendly attributes of the societies in which older people live—they correspond to societal resilience. On the other hand, Glaser et al. (2009) suggest three domains of the well being of older persons as income, health, and social support to reduce the vulnerabilities of poverty in old age.

The routes into low income in retirement were shaped by one or more of the following: low earnings in employment, minimal financial planning for retirement and the impact of key life events on this planning, such as divorces and deaths. A sustained growth in earnings should eventually lead to lower poverty rates among the elderly. Bardasi et al. (2002) suggest the importance of income and effects of having low income on poverty at old age. In developed economic systems, those with high household income often consider themselves and their employers as the most important sources of retirement income whereas; households with lower incomes report the government and their families as most important (HSBC, 2008). Besides, retirement preparation among those employed influences income during old age. Moen et. al., (2006) discover that spouses' decision making in the form of retirement planning tends to be positively related to lower poverty at elderly.

Rowland and Lyons (1996) found that poverty rates increase with age and nearly one-fourth of elderly women were poor, reflecting their lower wage levels during working years, their increased of financial stress from widowhood and longevity that exceed savings. In addition, poor elderly are less likely to have family or companions living with them who can assist with their medical and financial needs. Similarly, Millward (1998) suggested that the most at risk of significant poverty include those over the age of 80, women, those living alone and disabled elderly persons. However, Zaidi and De Vos (2008) further argue that the employment record during working life is critical in many contexts, because entitlements to pensions in most schemes are accumulated with the help of the social insurance contributions deducted from wages. People accumulate wealth over their working lives to finance consumption after retirement (Friedman, 1957). Thus, the longer the employment period increase the amount of saving for their retirement. The occupation and type of job held also matters, because both levels of earnings and the likelihood of pension coverage in the employment sector affect the accumulation of pension entitlements. With lower level of educational attainment, older persons have limited economic opportunities and this eventually affect their ability to continue work, earned incomes and to some degree, savings and wealth (Jariah and Sharifah, 2008).

For many reasons, for most people the income potential diminishes after a certain age and then poverty is more likely to occur. In addition to improper financial planning and employment status, a number of other factors also are pointed out to an urgent need to address. Rake et al. (2000) discovered that lower retirement incomes for those women who had children, and for those who divorced and did not remarry. These findings were supported by Ginn (2003), Walker et al. (2000), and Johnson and Favreault (2004), which showed a significant loss of pension entitlements among women who had children and who experienced marital disruptions. In apparent contrast to these studies, Bardasi and Jenkins (2004) and Sefton et al. (2008) found that marital history appeared to make no difference to pension income in old age once other factors were accounted for. On the other hand, past study reported that poverty among the elderly in rural areas is much higher than in urban areas, men reported receiving twice as much income compared to women and higher levels of income for men are clearly associated with enhanced levels of educational attainment (Masud & Haron, 2014).

Demey et al. (2013) argued that those mid-life men who have not had children, have no educational qualifications, are not economically active and who live in rented housing were likely to be most at risk of needing a social and economic safety net in old age. Some have reported no relationship between divorce and help given or received in old age (Pezzin and Schone 1999). However, others have found that older divorced or separated parents were more likely to receive help from children compared to those who are still married (Glaser et al. 2008). Researcher such as Johnson and Favreault (2004) argued that there is a significant loss of pension entitlements among women who had children and who experienced marital disruptions. In the same vein, other research also has shown that marital disruptions over the life course may have adverse consequences for social support and connectedness at older ages.

In Malaysia, the retirement age was 55 (Muhamad and Kamis, 2002) and nearly 70% of the Malaysian retirees received less than RM 500 per month (Ithnin, 1995). Employees Provident Fund (EPF) in Malaysia was established to reduce the poverty among elderly who were working before. Unfortunately, it does not adequately address poverty among older persons (Olsen, 1994). Many of elderly still need to work at retirement age and need careful financial planning in earlier years. A common problem among Malaysian workers is that they tend to spend first and save the balance, whereas you have to encourage people to save first and spend only the balance. Currently only about 10 to 20 per cent of Malaysians are considering non-mandatory retirement savings and investments to supplement their EPF contributions. The concern with low retirement savings is compounded by the fact that it is the only significant form of savings for most Malaysians, due to rising cost of living and wage stagnation. Elderly have less working capabilities and have limited sources of income due to the lower education level (Mat and Taha, 2003). As such, most of Malaysian elderly depended to their adult child to support them but those whose children do not have enough money to support them, have serious problem to manage their living costs (Mazanah and Mazalan, 2002. With declining support from children and other family members due to rapid-socio-economic and

demographic changes, many older persons may indeed end up with financial problems. Hence, older age is an important period when elderly persons stretch their limited financial resources and deal with many complicated financial management tasks.

V) Proposed framework and hypothesis development

The absolute concept of poverty means one's inability to obtain minimum necessities to maintain physical efficiency or to fulfill basic human needs (Jamilah, 1994). According to Deaton and Paxson. (1998), poverty is a syndrome affecting people in situations characterized by malnutrition and poor health standard, low income, unemployment, unsafe housing, lack of education, inability to acquire modern necessities, insecure jobs, and a very negative outlook on life. Based on the review of past literature, this research suggests four main factors that cause the elderly poverty. These are improper financial planning (income and saving), social-demographic factor (employment status and education), inadequate government support (retirement age, social security and health) and lack of social support (family, community). Figure 1 shows that the factors the causes the poverty at old age.

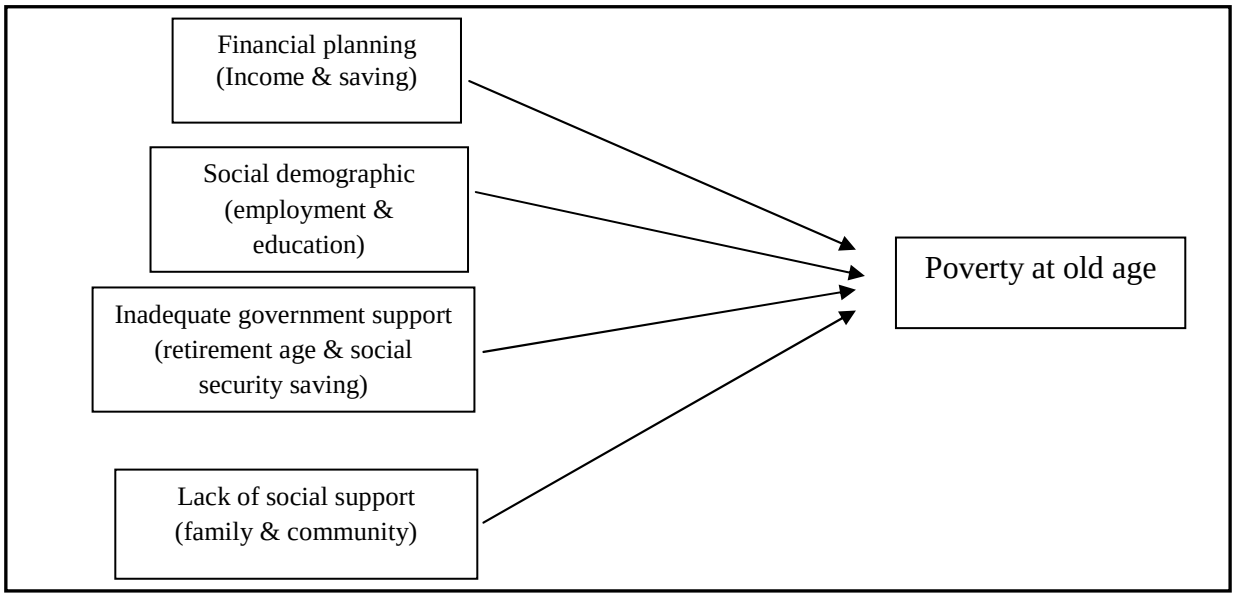

Figure 1: Framework of factors that cause the poverty at old age

Many elderly households do not have adequate savings for post-retirement expenses (Helman,R., 2005). Due to insufficient retirement funds, many elderly persons are confronted with serious financial problems (Gardyn, 2000). A survey on elderly in public service shows that elderly in Malaysia anticipate financial constraint to be the major challenge upon retirement (Muhamad and Merriam, 2000). Many of elderly still need to work at retirement age as they do not have careful financial planning in earlier years. Based on this statement, the research proposes as follows.
Proposition 1: There is relationship between improper financial planning (income and saving) and elderly poverty.

Older people might be poorer just because they are less educated than the younger generations.
Due to the lower education level, elderly have less working capabilities and have limited sources of income (Mat & Taha, 2003). Therefore, this research proposes as follows.

Proposition 2: There is relationship between social-demographic (employment status and education) and elderly poverty.

Government's ability to manage a social security system is important in determining the system best suited to a country. Many countries have had serious problems managing their social security systems and consequently lead to elderly poverty (OECD, 1998). Financial constraint is the major challenge upon retirement (Yaacob, and Nurdin. 2000.). Thus, the research proposes as follows.

Proposition 3: There is relationship between inadequate Government support (retirement age, social security, and health) and elderly poverty.

Most of Malaysian elderly depend to their adult child to support them but those whose children do not have enough money to support them, have serious problem to manage their living costs (Merriam and Mohamad, 2000). Although allowances from children significantly reduce elderly poverty, it is not clear whether this practice does indeed last in the long run. Thus, the research proposes as follows.

Proposition 4: There is relationship between lack of social support (family, community) and elderly poverty.

VI) Future directions for retirement plan

Old-age financial protection has become a key focus of policy interest and research efforts in South-East Asia, including Malaysia. In developed countries the combination of strong social security systems, well-developed capital markets, and small households contribute to higher living standards for the elderly. Due to demographic, social and economic changes, there is a need for effective system in income provision for the elderly. Reliance on traditional means of family support combined with individual savings may not reduce the poverty at old age. To prevent such a scenario, action needs to be taken to ensure that all workers are covered by a system that offers a minimum guaranteed income through periodical payments. However, any such reforms are dependent upon the political will of government to address such concerns.

Government should provide assistance through effective public policy to protect the welfare of the elderly, involvement of private entities through corporate social responsibility, encourage both formal and informal sectors for voluntary savings, ensuring the adequacy of savings to support post-retirement living, and create the awareness of the benefits of savings from young through early education in schools and parental guidance (Samad, 2013). Indeed, most developed countries have introduced policies and organizational practices that target older workers, including: reducing incentives for workers to take early retirement, encouraging later retirement and flexible retirement, passing legislation to counter age discrimination and helping older workers find and keep jobs (The conference board of Canda, 2016). As the number of elderly grows annually, their demand for healthcare also relatively increases. Hence, in the future, Malaysia government should build more hospitals and clinics especially in the rural area to cater the huge healthcare demand from the elderly.

Lifelong learning has an important potential contribution to poverty reduction. Individuals engaged in lifelong learning are more likely to improve their livelihoods through better employment opportunities, higher income, broader understanding of financial markets, better health and healthier behaviors, access to health services, knowledge of health conditions, among others. Therefore, government must work hand in hand with private sectors to ensure in maintaining the skills of the current workforce; upgrading the skills of those with the greatest needs to increase their employability; and allowing adults to re-skill to find employment in other areas (Sabates, 2008).

It is important for one to have sufficient financial knowledge, as it would help in understanding one's own financial status. Those who have financial knowledge can have well prepared financial planning for the future (Joo et al., 2004) and thus can avoid poverty at old age. Thus, government should establish a government-linked institution body to create the awareness throughout the country and provide professional advice to the citizens. In addition, government should make it compulsory for the higher education learners to take the financial planning as a required subject or co-curricular

activities. Besides that, both public and private companies should provide the training on financial planning for the working people. The practice will not only help them to prepare for better future financial planning but also indirectly help to country economy growth.

Children in Asia were generally positive and responsible towards their elderly parents. These elderly parents are being cared for not only financially, but also in the form of food preparation, purchase of daily necessities, housekeeping, doing laundry and transportation to visit relatives/hospital/clinic (Chor & DaVanzo, 1999). In many other regions, such as Singapore, China, the United States and Canada, adult children are required by law to support their elderly parents. Legislation of parental support explicitly states that it is the responsibility of the family, rather than the government, to care for their elderly parents. This legislation of parental support and practices should also imply in other Asia countries like Malaysia where still value the closed knitted family. That will help the elderly to have comfortable life with people surrounding them. In addition, every community in the region also must play a role in ensuring that elderly are well taking care of.

Abstract

The theoretical principles of modern marketing paradigm - relationship marketing are developed. The definition of relationship marketing is given. It is noted that the main aim of relationship marketing is constructing, maintaining and developing the privileged relationship with the company's stakeholders to obtain the mutual benefits and assistance to society. The definition of a privileged relationship is introduced. The concept of relationship marketing principles is clarified and developed: the principle of knowledge and accounting of the relationship factors; the principle of emphasis on creating positive feelings, emotions, feelings and moods; the principle of the new marketing mix. The necessity of the application of psychology in marketing is justified. Given the relationship marketing environment, we propose a new element of the marketing - a psychological approach. Application of psychological approach will allow employees of any company better understand and accurately meet the real needs of customers and other stakeholders.

Keywords: Relationship marketing, privileged relationship, relationship marketing principles, marketing complex, psychological approach

Introduction

Currently, relationship marketing is a subject of current debate among theorists and practitioners of marketing around the world. It is in the end of XX -beginning of the XXI century, a large number of supporters of this concept appeared which is based on the relationships with key market partners. Every year the number of supporters of the concept grows. The interest from the scientists to the relationship marketing concept, which differs from the concept of traditional marketing, acts an effective force for its further development. Note that the theory of relationship marketing is in its infancy and development. An interesting and true, in our opinion, is the opinion of S. Kush Chof the coexistence of two paradigms in the current context of social development (2008) - the traditional marketing and relationship marketing. It is known that the traditional marketing concept is still relevant to a number of companies due to objective reasons. However, in our opinion the struggle between the traditional concept of marketing and the concept of relationship marketing was won by the latter concept. The aim of the article is to develop theoretical relationship marketing positions. To achieve the goal it is required to achieve the following objectives: to define relationship marketing; to clearly define groups of stakeholders with whom the company must build relationships, to designate the purpose of relationship marketing, to clarify and develop the principles of marketing relationships, to justify the necessity of application of psychology in marketing and to define the psychological approach.

Relationship marketing - modern marketing paradigm

The essence of modern marketing concepts

In scientific literature of marketing there are a lot of definitions of relationship marketing. However, there is no a single generally accepted opinion in the definition of relationship marketing. On the basis of the relationship definitions of marketing analysis (2004, 2008), we have three identified substantive items, which should contain a modern relationship marketing. Firstly, extensive interpretations of priority relationship marketing. We prefer a broader interpretation of the definition of relationship marketing to become more understandable by the reader. Second, the vision of relationship marketing as a marketing paradigm, not as a concept. Relationship marketing seems to be not only a self-concept and paradigm. We tend to refer to the concept of relationship marketing as a new marketing paradigm, as the status of the concept of "paradigm" emphasizing the priority of its importance and significance. Third, we focus on building relationships, not only with customers, but also with other groups of person. For the development of a strong partnership network the company must take into account the needs to maintain cooperation with the different stakeholders. The company should win the competition through the establishment and improvement of long-term relationships with all its stakeholders. There are many viewpoints which groups of individuals should companies build relationships with. Based on the review of the literature provided by the issue of (2004, 2015, 2008), we offer the following list of stakeholders.

Firstly, we concern the customers. In most cases, the relationships of the company-customer are the main focus of marketing science. In our opinion, a crucial factor in business success is real love for customers. It is important to know the factors of customer relationships. It is necessary to focus efforts on what we can do for the customer, rather than on what you can get from a customer. Currently, it is the client capital which valuable and desirable for any company.

Secondly, we speak about employees. The employees can meet customers' needs and satisfy their own needs. It is important to have a properly organized system of staff remuneration. We believe that the construction and development of high-quality relationships with employees allows the company to motivate and retain employees, which are qualitatively different needs of customers, are committed to the principles of relationship marketing, and follow the company's mission. The importance of human capital is undeniable.

Third, we take into consideration business partners. This group is one with whom the company communicates in the course of their business activities - distributors, dealers, suppliers, banks, advertising agencies, competitors, etc. We believe for development of strategies for creating and maintaining relationships with business partners, it is advisable to divide the relationships into vertical and horizontal. As it is known, the vertical relationships combine parts of the supply chain - suppliers, manufacturers, intermediaries. Horizontal relationships arise between the organizations occupying the same position in the channel of distribution and seeking cooperation to achieve mutual benefit.

Fourth, we concern members of the financial community. This group should be classified as shareholders, investors and analysts. In view of the difficult economic situation, it is a significant development of mutually beneficial relationships with the financial community. We believe that companies need to be learnt to develop and present a profitable investment projects, attracting foreign investors, have common views with shareholders.

Fifth, we mention the members of the scientific community. In a view of the rapid scientific and technological progress, we identify this group separately. It is important to understand the feasibility of investing in research and development. We believe that for many companies is important to develop and strengthen relationships with scientists from different fields of science. The close relationship between the company and representatives of the scientific community will produce brand new and desirable products and sell them on the market at the best conditions for.

Sixth, we speak about the group which is called “needy". We believe it is important the presence of the social dimension in the modern concept of relationship marketing. For this reason, we offer to mark the sixth group of stakeholders. By the "needy" we should interpret natural persons, legal persons, animals, which are objectively in need of material or moral support. To this group we offer to refer sick children, single parents, disabled, pensioners, people with no particular location of residence, social institutions, charitable organizations, medical institutions, environmental organizations, educational institutions, animal shelters, etc. The purpose of interaction with "needy" is the solution of important social problems.

Based on the identification of the three main marketing positions, it is possible to give a definition of relationship marketing. Relationship marketing - is a modern marketing paradigm, which is based on the construction, maintenance and development of privileged relations with the company's stakeholders (customers, employees, business partners, members of the financial community, the scientific community, "needy"), especially the key, by addressing a wide range of needs and demands of society.
The novelty and features of this contact determination are as follows:

Firstly, as a marketing paradigm. The perception of a relationship marketing paradigm involves allocating a significant place in the relationship marketing theory and practice of marketing. Relationship marketing can be perceived as a concept and as a paradigm. Two approaches are not mutually exclusive.

Secondly, as the emphasis on building of privileged relationships. We believe that a privileged relationship must be understood as long-term, mutually beneficial, trust, securities, sincere and positive quality of a relationship, which is a valuable competitive advantage for companies by allowing to develop in a dynamic market environment and to occupy leading positions in the market.

Third, as the importance of customer segmentation and value of key customers. In our opinion, in the context of relationship marketing segmentation it becomes especially valuable to select customers by psychographic or psychological principle. In this segment the customers are divided into groups on the basis of membership of a social class, lifestyle or personality characteristics. Sellers must be able to draw up a qualitatively psychological portrait of the client. In our opinion, the psychological portrait of the client should be composed of three faces, based on these theories: the theory of temperament, Socionics theory and the theory of perception of the world

Fourth, as the emphasis on building relationships not only with customers, but also with groups of persons. Marketing must recognize the importance of customer relationship management, but understand the needs to develop relationships with various stakeholders’ groups.

Fifth, as a designation of a particular group of stakeholders with whom you need to build a privileged relationship - members of the scientific community. Realities of the twenty-first century need to establish close relations with the scientists. We believe that only by developing and strengthening relations with the representatives of the scientific community it is possible to have positive synergistic effect in terms of creating new products, innovation, resource-saving technologies.

Sixth, as the designation of a particular group of stakeholders, who should be provided by a financial and moral support – “needy” We believe that the social aspect in the current understanding of the relationship marketing concept is underdeveloped. It is important that the relationship marketing company supporters showed concern for the community and assisted in “needy."

Seventh, as the designation of the main ways of building relationships, the needs satisfaction of a wide range of stakeholders and society. It is desirable that the company's employees tried to meet the needs of stakeholders who are at high levels. The more refined the stakeholder needs will be met, the higher the level of welfare of the stakeholders, the more loyal they will be to the company, the more profitable the company will be. Meeting the needs of society will contribute to the realization of self-worth in the face of the company, the formation and strengthening of a positive image in the public

eye (2015). In this regard, it is important to study and propose a competency model for modern vendors selling various goods. For example, we offer an ideological model of competencies for sellers of real estate, vehicles, computer equipment, clothing, jewelry, etc. A good example of universal competence model can be considered a model consisting of twenty-four competences and seven clusters of competence (2015).

The purpose and principles of relationship marketing

In our view, the aim of relationship marketing is building, maintaining and developing the privileged relationship with the stakeholders of the company in order to obtain the mutual benefits and assistance to the community. We believe that the purpose of modern marketing paradigm should contain social aspects. We underline that care about society - a trend of the economy of the XXI century. Private company determines which groups of individuals and what tools should be built privileged relationships with. For other companies strengthen ties with customers and an employee is a priority. It is important to understand that the result of interaction between the company and stakeholders is two side benefits, not just one.

There is a need to develop ideas about the principles of modern marketing paradigm. In marketing literature there are some principles (2004, 2003). We offer the following marketing principles of relations based on our definition of relationship marketing:

1. The principle of staff training with the help of modern technologies.

2. The principle of creating conditions for self-knowledge, self-development and self-employees.

3. The principle of the application of interdisciplinary approaches in marketing.

4. The principle of targeting key customers and partners.

5. The principle of orientation to the constant contact with customers and other stakeholders.

6. The principle of complement contact "face to face".

7. The principle of the preliminary finding information about stakeholders before communication.

8. The principle of universal interaction.

9. The principle of creating a common strategy for working with customers and partners.

10. The principle of the value of personal contact between the stakeholders and employees of the company (the company).

11. The principle of emphasis on creating stakeholders in the positive sensations, emotions, feelings and moods.

12. The principle of emphasis on customer service.

13. The principle of knowledge and taking into account the relationship factors with different groups of people.

14. The principle of importance of segmenting customers based on behavioral and psychological factors.
15. The principle of use of information about clients and other stakeholders from various sources.

16. The principle of identifying and meeting the needs of a wide range of stakeholders.

17. The principle of the application of creativity when working with partners.

18. The principle of forming a positive image of the company (employee).

19. The principle of emphasis on high quality of goods (services).

20. The principle of providing quick answers to customer questions and other partners.

21. The principle of veracity in communication with partners.

22. The principle of long-term, mutually beneficial cooperation and trust.

23. The principle of conquest comprehensive partner loyalty.

24. The principle of distribution to customers and other partners of unexpected bonuses.
25. The principle of orientation on customer retention and key stakeholders.

26. The principle of the company's mission reports to clients and all partners.

27. The principle of the creation of joint value to customers and stakeholders.

28. The principle of evaluating the effectiveness of elements of integrated marketing communications.

29. The principle of concern for society.

30. The principle of monitoring customers' opinions and stakeholders.

31. The principle of rapid feedback from customers and business partners.

32. The principle of work on our mistakes.

33. The principle of individual approach to every customer and business partner.

34. The principle of building relationships with six groups: customers, employees, business partners, the financial community members, members of the scientific community, "needy."

35. The principle of applying a new complex of marketing.

Following the present principles will promote a growth of the main indicators characterizing the effectiveness of marketing and business in general. We believe that it is necessary to conduct research for the finding a new set of marketing requirements. The Concept "4Ps" was really good, important and popular to a certain extent. Taking into account the change of traditional marketing to relationship marketing is important to recognize the need to change the look of the classic marketing mix "4Ps". In our view, the principle of the application of interdisciplinary approaches in marketing activities is one of the most significant. We believe that the successful development of relationship marketing is associated with the use of theoretical and practical development of such sciences as psychology. It is important to justify the necessity of psychological application in marketing.

The importance of psychological application in marketing activities

Commerce psychologisation is one of the actual market trends. We believe that a deep understanding of customers and other stakeholders of the company is the only solid basis for creation and development of a successful business. According to many scientists, the main marketing object - is the study of consumer psychology. Experts have proven that 95% of human thinking takes place at an unconscious level through memories, emotions, thoughts, and other components that people do not

realize (2003). Consumers can not precisely determine the forces that influence the decision to buy and are not able to describe them verbally. This is indicated by various methods of measuring physiological functions, which confirm the activation of brain cells proceeds the moment of awareness and activation of the parts of the brain that are responsible for verbalization. These areas of the human brain are activated when a person has unconsciously decided to express his thoughts orally. We believe that it is important to study the psychology not only consumers, but also the psychology of all stakeholders to develop high-quality relationships and obtain benefits by both parties of material and immaterial nature. In this context we offer to apply a psychological approach in the marketing activities. Under the psychological approach it should be understood an approach of the employee or the campaign itself to stakeholders, or any issue, problem, company decision based on knowledge of mental processes (sensation, perception, memory, thinking, imagination), mental states (tension, motivation, frustration, emotions, feelings) and mental properties (orientation, abilities, inclinations, character, temperament) of people. It is advisable to briefly consider four psychological concepts which are taken as a basis for marketing strategy, known throughout the world .In classic concept by Ph. Kotler (2003), the main role is played by the psychology of motivation and needs. This concept is called classical or needy-motivational. Thus, Ph. Kotler believes that marketing should promote the production of quality goods and services. In this case, efforts to promote the products should be minimal. Needs always exist objectively. Needs do not need to create artificially by means of manipulating the psychology of advertising or consumer. Requirements should be timely and accurately meet. A result of this process will be long-lived brands. The concept of J. Trout (2001), which is called marketing concept prevails general and social psychology. J. Trout believes that the main principle of marketing - is positioning the product in minds of consumers to be the best. The main thing - it's not the product itself, but efforts to fight against competitors. Here, the psychological basis of marketing - it does not work with the product and with consumers' images simultaneously perceiving and comparing different products. The concept of sensory marketing, founded by M. Lindstrom (2010), is based on the use of psychophysiology analyzers consumers and the psychology of religion. This concept is called sensory marketing and comes to two positions. First, any product should simultaneously affect the five sensory analyzers: sight, hearing, smell, touch, taste. Secondly, brand should arouse religious sentiments of the consumer. He must believe that he had bought the best that there is in the market. Neuromarketing concept proposed by J. Zaltman (2003) is based on cognitive psychology and neuropsychology. The author considers the concept to be the main thing in marketing - the management of the decision-making process of the consumer. The basics of the framework for the emergence of the concept of "cool" brands are incorporated in the human subconscious. They need to extract out as much information blocks as possible and return to the consumer in the form of metaphors. Application of psychological concepts in marketing by researchers world-wide is evidence of the appreciable increase of psychology in marketing. Relationship marketing implies the need to use theoretical and practical development of psychology in marketing for the construction, maintenance and development of the high-level relationships with stakeholders. The effectiveness of psychological portrait of the client is connected with allowance precisely and consistently interacts with customers. In turn, its use is guaranteed to lead to the construction of high-quality and effective communication with the client. In its turn, it leads to use of guaranteed-quality construction and efficient communication with the client. We believe that the basis of the client's psychological portrait should be based on four theories: the theory of temperament, Socionics, the theory concerning types of thinking and the theory of character accentuation. Despite rather serious research in the field of differential psychology, methodological approaches affecting psychological portrait of the client need to be improved.

Conclusion

Thus, theoretical relationship marketing principles are developed. Under the relationship marketing it should be understood a modern marketing paradigm, which is based on the construction, maintenance and development of privileged relations with the stakeholders of the company, especially the key ones, by addressing a wide range of needs and requirements of society. It is important to develop relationships with the following groups of stakeholders: customers, employees, business partners, members of the financial community, the scientific community, "needy". A key

aim of relationship marketing is building, maintaining and developing the privileged relationships with the company's stakeholders in order to obtain the mutual benefits and assistance to society. Meeting the needs of society should be considered an important part of the paradigm. In our opinion, it is important to take care of psychological well-being of stakeholders. In your opinion, K. Ryff (1989, 1995) most successfully revealed and described the phenomenon of psychological well-being. It is important to follow the principles of relationship marketing such as: the principle of conditions' creation for self-knowledge, self-development and self-realization of employees; the principle of the use of interdisciplinary approaches to marketing activities; the principle value of personal contact between the stakeholders and employees of the company; emphasis on creating positive feelings, emotions, feelings and moods; the principle of distribution to customers and other partners of unexpected bonuses, etc. It is important to study the psychology of consumers and all stakeholders to improve the relationship between two parties. It is advisable to apply a psychological approach in marketing activities of the company. We consider it important to conduct further research on a new set of marketing offerings, the creation of competency model for developing a method of creating a psychological portrait of the client.

Abstract

The evolution of the insurance market will undergo major changes starting with the 1st of January 2016, when the implementation of the Solvency II European Regulation takes effect. This regulation integrates new risks for the insurance companies: the underwriting risk, the liquidity risk, the concentration risk, the market risk, the credit risk, the strategic risk, which will all lead to the insurance company solvency establishment. In this context, we decided to realize an analysis of the structure of the investment portfolio of global and European insurers. Also we identified and analyzed trends, strategies and achievements in the insurance field.

Keywords: insurance, investment, portfolio, efficiency

Introduction

The most important effects of the Solvency II European Regulation are:

- ✓ changes in tariffs,
- ✓ mergers, takeovers or bankruptcies of insurance companies,
- ✓ the transformation of large companies into branches,
- ✓ great responsibility of any insurance company management, even direct responsibility from the part of the company manager,
- ✓ a new approach of the supervision process, at the European level, based on economic principles for the measurement of assets and liabilities, by taking into consideration the number and the variety of risks to which the company is exposed,
- ✓ the draw-up of insurance company rankings by taking into account, not the gross written premiums, that is the volume of sales, but the new indicator, i.e. solvency, indicator which is capable to disclose the company's ability to make payments in the future (future compensation, debts etc.).

This regulation also brings advantages, which, for the insurant, may be correlated with a reduction in the risk of bankruptcy for the insurer, the availability of innovative insurance products, a better correlation between the products offered and individual needs.

1. Trends, strategies and achievements in the insurance field

In most countries, insurance companies continued to allocate investment portfolios in bonds both in the public and in the private domains, an aspect which was encountered in all the insurance sectors. (Dreher A, 2006) Investments generate positive aspects, especially in the life insurance sector. The main strategies adopted by the insurance companies were:

- investment in bonds
- investment in shares
- investment in the real estate domain.

Insurance companies can approach the most profitable investment strategy, i.e. investment in bonds. Bonds continue to dominate the life insurance investment portfolio. (Chien Chiang L., Chi-Hung Chang, 2015)

In 2014, the insurance market from 13 countries (Columbia, France, Hungary, Israel, Mexico, Peru, Portugal, Puerto Rico, Slovakia, Spain, Turkey and Uruguay) allotted 75% of the investment in bonds (figure no 1). In countries such as Hungary, Italy, Slovakia, Turkey, the investment portfolio from the life insurance sector was greater than 85%, the sums of money being invested in bonds. In figure no 1, it may be noticed that, out of the European countries, Turkey has the biggest investment portfolio, with 93.1%, being followed by Hungary with 90.8%. At the opposite pole, there is Finland, with 27.9% of the total investment allocated to bonds.

On the other hand, other countries reported that insurers applied the share investment strategy. In this respect, in Europe, insurance companies from Denmark (52.7%), Iceland (28.5%), and Sweden (36.9%) allocate over 30% from the investment portfolio, the biggest allocation being in Denmark. In countries such as Indonesia, Panama, South Africa over 60% is allocated from the share investment portfolio. In some statistics, the allocated percentage is much bigger due to the inclusion of investment in mutual investment funds (for example, in Panama, the percentage is 78% according to figure no 1). Another strategy, adopted by the insurance companies, is the investment in the real estate domain. Nevertheless, this strategy was adopted on a small scale, Australia, Chile, Norway and Switzerland being the only countries in which the insurance companies invested between 10 – 15% (figure no 1).

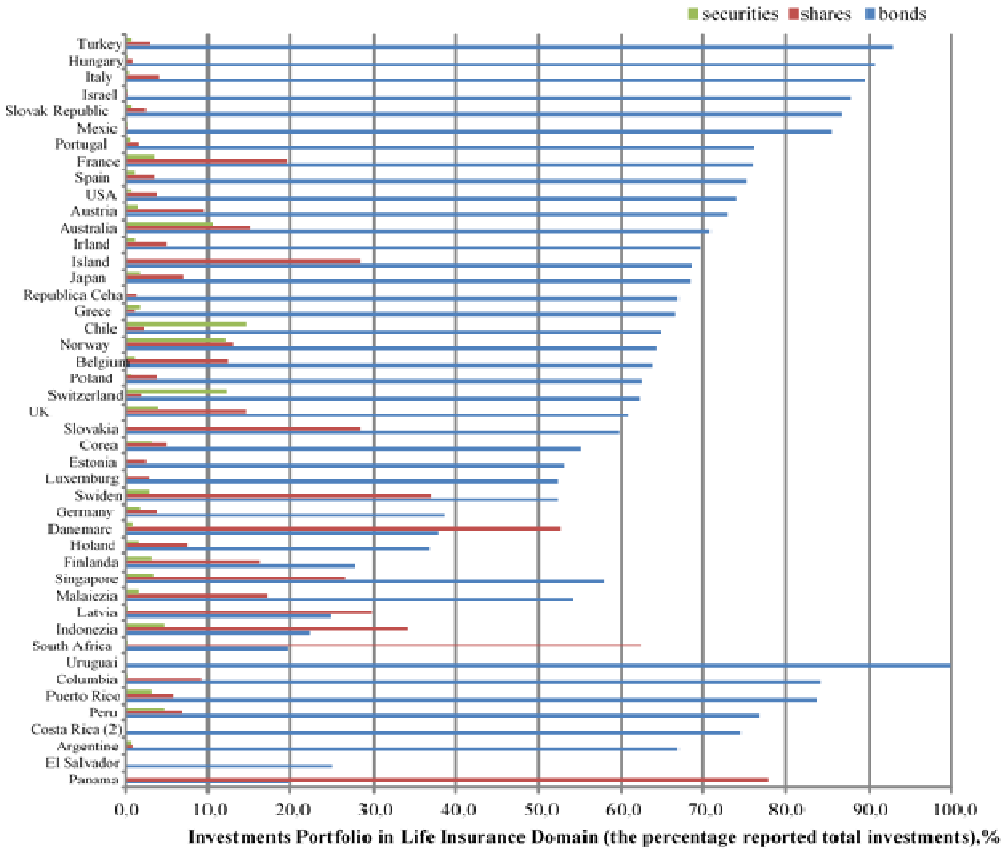

Figure 1: Life insurance - investment strategies (data processed from the OECD Insurance statistics 2014 source)

As far as the investment trends and strategies regarding general insurance are concerned, most countries have stability in investment in shares or in other assets. In 2014, an increase of 5 – 14% was reported regarding the allocation of investment in shares in Iceland and Indonesia. The achievement of great performances for some insurance companies from different countries (Denmark, France, Greece, Iceland, Ireland, Israel, Italy, Luxembourg, Norway, Sweden and Switzerland) entailed investment strategy modifications, from investment in bonds to investment in shares and other assets. Nevertheless, the strategy to invest in bonds dominates most countries, occupying over 75% from the general insurance investment portfolio in Canada, Columbia, Hungary, Italy, Mexico, Paraguay, Puerto Rico, Turkey and Uruguay.

In Europe, the biggest fund allocation for investment in bonds is reported in Hungary with over 80% (figure no 2). Austria allocates 41.2% of the funds for investment in shares, Poland and Germany 66.02%, that is 75.2% less, whereas Finland and Sweden reports over 30% of the total investment portfolio. The general insurance fund investment strategy in the real estate domain is applied only by a few countries and the funds are limited. Thus, Finland, Italy, Slovenia, Spain and Portugal invest between 7-10% of the funds, the first place being occupied by Spain with 9.99%, followed by Portugal with 8.8%.

These investment strategies allow insurance companies to collect real net income. According to statistics, in Hungary, Iceland and Luxembourg, insurance companies collected bigger real net

income from investment in 2014 with up to four percentage points as compared to the previous year. In Poland, life insurance investment income was with up to 5% bigger, whereas in Israel there was a drop, but the benefits of the approached strategies were positive.

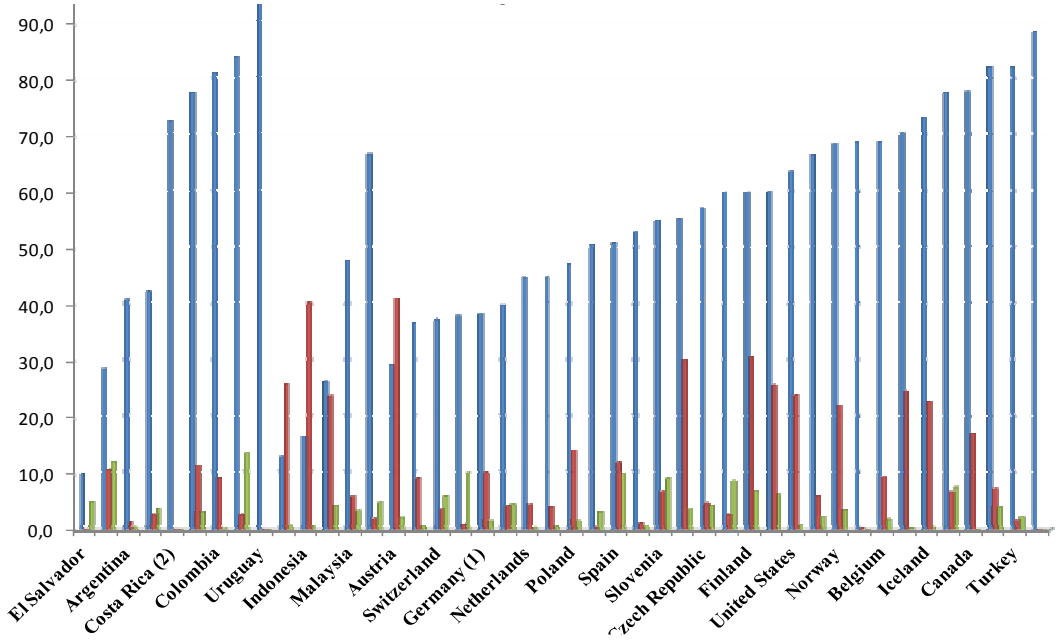

Figure2: General insurance fund investment strategic elements

(Report for the year 2014 - Adaptation after the OECD Insurance Statistics 2015 source)

Regarding return on equity for insurance companies, there has been reported a variable situation from year to year. In 2013, the best evolution of the life insurance return on equity (ROE) was recorded in Greece, Italy and Portugal, which passed through the same economic instability periods generated by the financial crisis. Therefore, the life insurance sector in Portugal recorded the best evolution (from 7.8% in 2011 to 30.6% in 2014). Other countries, from 2012 until 2014, recorded moderate increases between 5 and 10%.

In the general insurance sector, the return on equity varied. Insurance companies from Slovakia achieved a growth from a negative percentage of -43.5% in 2011 to 27% in 2014. In Greece, Finland, Iceland, Poland, the return on investment was of over 10% in the analysed period. France recorded a decrease of 49% in 2012 as compared to 2011 regarding ROE, and in 2013 it recorded a comeback at 7.4%. Switzerland reported an increase of 39.5% for the year 2013 as compared to 2011. Ireland recorded a decrease of almost 43% in 2014 as compared to 2013 when the general insurance reported percentage for ROE was of 16.1%.

2. Insurers' investment portfolio in Europe

Europe is the place of developing modern insurance and remains a key global market, with rapid growth especially in the branches of life insurance and savings, but ranking second after the United States. Developing a European insurance market was a gradual process that lasted several years. EU directives on insurance represent generally accepted principles in the European Community in order

to standardize insurance rules and facilitate international trade, referring primarily to the insurance business, but also to the reinsurance domain. (Novac L.E, 2008)

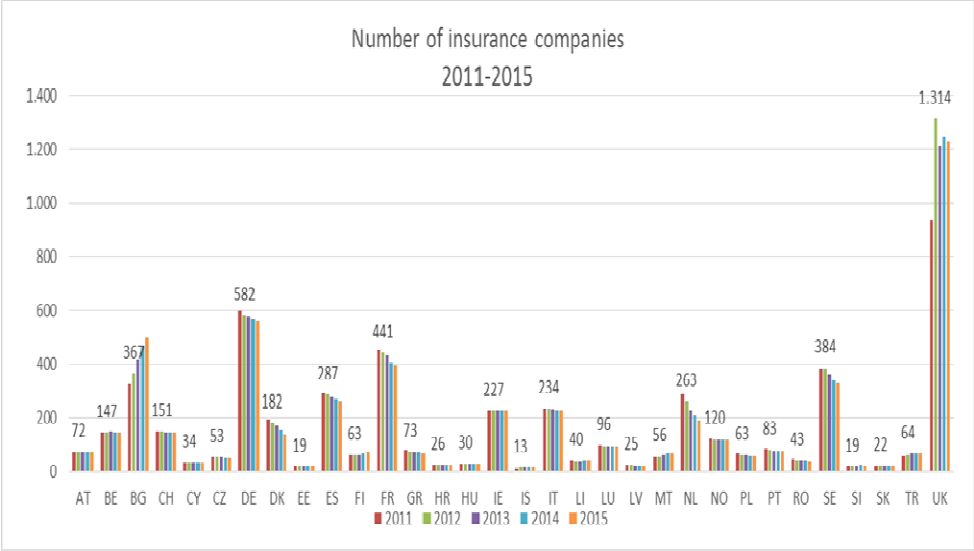

Figure 3: Number of insurance companies in Europe (Adaptation after the Statistics n°50 European insurance in figures)

As we can see in Figure no 3, the highest number of insurance companies in Europe, recounted in the UK (1314 insurance companies), followed by the Germany and France. Insurance is a key sector of the European economy, whose influence is felt both in protection against risks in the economic and social landscape of the member countries, the role of stimulating the idea of saving the medium and long term, and as a provider of funds for financial markets. Incidentally, another role Obligatory insurance is the development of techniques for asset management and risk management.

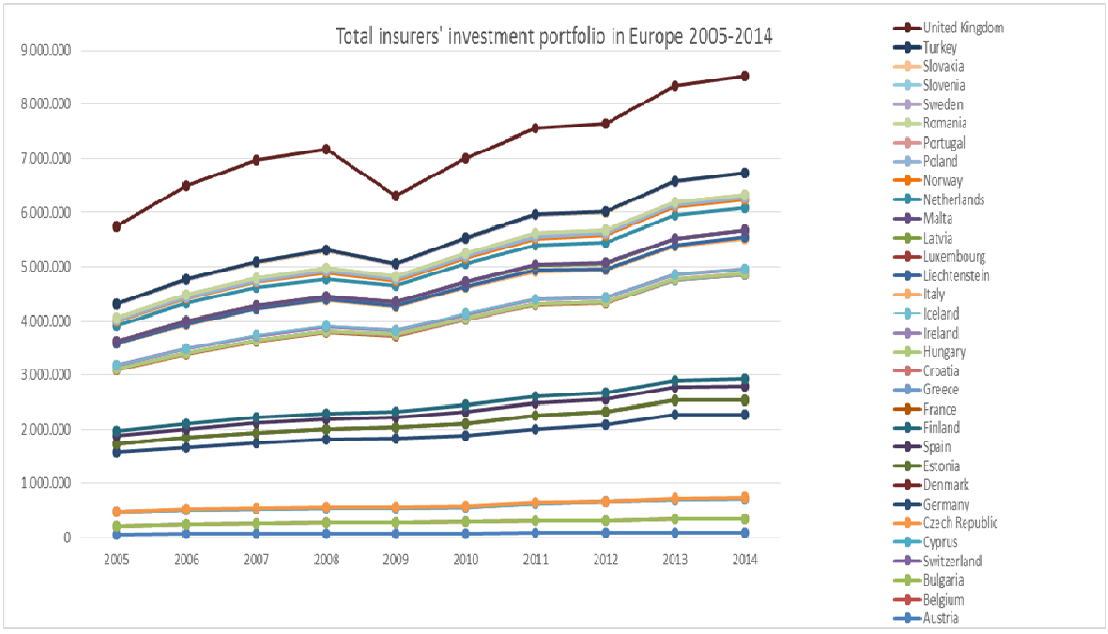

Figure 4: Total insurers 'investment portfolio in Europe (Adaptation after the Statistics n°50 European insurance in figures)

We can observe in figure no 4 that the investment portfolio of insurance companies knows an ascending evolution. Investing activities related to the formation of the investor portfolio investment, which may include different types of investments. The investment portfolio represents all real investment objects and financial (groups of assets such as stocks and bonds, etc.), held by the investor in order to achieve investment activity in line with established investment strategy. Management of securities investment portfolio includes all principles, methods and tools of return on these assets financial crossing the structure of the portfolio less effective structure and operations more efficient.

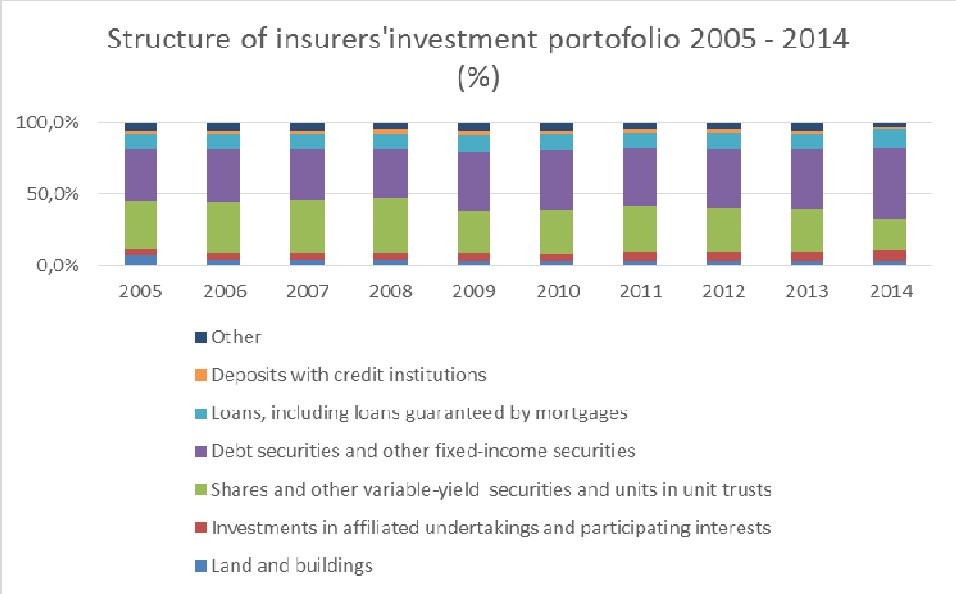

Figure 5: Structure of insurers 'investment portfolio (Adaptation after the Statistics n°50 European insurance in figures)

As we can see in figure no 5, the structure of the investment portfolio of insurers in Europe, the largest share is held by debt securities and other fixed-income securities, followed by shares and other variable-yield securities and units in unit trusts. Portfolio composition is a result of the firm's position risk, expectations developments related income securities (which are subject to financial market developments in interest rates), the fiscal situation and the need immediate liquidity. Performance of a portfolio is determined by comparing yield obtained with the rate of return on financial market. Also, we can observe the constant maintenance of the loans, including loans guaranteed by mortgages.

Conclusions

Globally, insurers do not generate systemic risk, insurance having a stabilizing effect on the economy, due to long-term investments and prudent investment policy, even conservative. Indirect effects, related primarily to the decline in indices, changes in interest rates and ratings of financial instruments, reducing profit margins and in income from hedge "zero" were much stronger in the case of life insurance than those General. Insurer's exposure to "toxic" assets was relatively low, mainly due to conservative investment policy, provisions and restrictions imposed by national legislation on asset investment, portfolio diversification, ban or limit investment in alternative instruments. In the post-crisis period with loss insurers were 261 billion, compared with USD 1 230 billion in banking,

21% (Chien-Chiang Lee, Chi-Hung Chang, 2015). Profitability fell insurance, primarily in life insurance by reducing investment performance due to falling indices and volatility of financial markets.

Abstract

The concept of sustainable development has been crystallized in time, over several decades, in some depth internationally scientific debates, and acquired precise political meanings in the globalization context. For Romania, as an EU member state, sustainable development is one possible option, but the only rational perspective as a nation, resulting in the establishment of a new development paradigm at the confluence of economic, social and environmental factors. Once accepted that most serious problems of environment are related to the use of renewable natural resources in the production process, we can admit the need to discuss issues related to economic policies that allow optimum implementation, their impact on the economy and, in particular, the contribution in promoting technical progress. Based on these considerations, in this paper, the main objective was to identify those characteristics of sustainable development in the mining industry in Romania, so in the specific conditions of our country, connection to the transition to the new model of sustainable development our country is engaged alongside the other European Union Member States, must be matched by additional national effort to recover some substantial gaps in several areas of the national system.

Keywords: sustainable development, oil, natural gas, coal

Introduction

As a result of injudicious interventions (industrial pollution, especially mining, oil and chemicals industry, storage of waste, faulty agricultural works, failure to deal with erosion), compaction, deterioration of soil structure, depleting substances nutrients often occurs, leading to lower soil fertility in agriculture.

Major consequences for natural capital made by such plans and sectoral programs performed in the absence of a coherent overarching strategy that reflects the complexity of direct and indirect interdependencies between socio-economic and natural capital components at different scales of time and space are found in a number of significant changes in qualitative and quantitative structure and operation of the latter.

To act realistically, knowingly, on the strategic direction towards sustainable development, for Romania (1), its citizens and its foreign partners is necessary to have a clear understanding on the starting point to the road, the real assets of the country, but also on defects inherited from a complicated historical background. Therefore, Romania's specific circumstances, the connection to the transition to the new model of sustainable development in which the country is engaged alongside

the other Member States of the European Union, it must be matched by additional national effort to recover some substantial gaps in several areas of the national system.

For Romania, as a EU member state, sustainable development is not one possible option, but the only rational perspective as a nation, resulting in the establishment of a new development paradigm at the confluence of economic, social and environmental factors.

1. Literature Review

The concept of sustainable development crystallized in time, over several decades, during internationally scientific debate and acquired precise political meanings in the context of globalization.

In recent history, the first signal that the economic and social developments of both countries all over the world and of humanity as a whole can not be separated from the consequences of human activity on the natural environment was made in the 1972 Report of Club of Rome entitled "The Limits to Growth" (Meadows Report) (Meadows *et al.*, 1972). The document summarized the data on the evolution of five factors (population growth, impact of industrialization, pollution, food production, and natural resource depletion trends), suggesting the conclusion that the development model in that period can not be sustained on long term.

For about four decades - namely, the oil shocks of the 1970s – it was established the idea that oil production is an inevitable decline. The influent paper of the Club of Rome predicted the collapse of an industrial system confronted to an exponential growth in energy demand, with growing overpopulation, and pollution. Two years later, National Geographic (Grove, 1974) popularized the theory of peak oil production, of the American geologist M. King Hubbert, who forecasted that the absolute peak of oil production will be reached in 1995, after which alternative forms of energy should be necessary to offset the rapid decline of hydrocarbon-based economy.

The issues regarding the relationships between humankind and environment became a concern for the international community since United Nations' first Conference on Environment (Stockholm, 1972) and resulted in the work of the World Commission on Environment and Development, established in 1985. The report of this Commission presented in 1987 by G. H. Bruntdland and named "Our Common Future" (Bruntdland Report, 1978), offered the first accepted definition of sustainable development as "the development that meets the needs of the present generation without compromising the ability of future generations to meet their own needs". The concept of sustainable development proposes an integrated approach of policy and decision makers in which environmental protection and long-term economic growth are seen as complementary and mutual interdependent.

From this point, the complex issues related to sustainable development acquired a global political dimension being addressed at the highest level at the World Conference on Environment and Sustainable Development in Rio de Janeiro (1992), at the Special Session of the UN General Assembly, by the Millennium Development Goals (MDG) approach (2000), and by the World Conference on Sustainable Development in Johannesburg (2002). Thus, they have outlined concrete action programs at global and local level (Local Agenda 21) according to the principle "think globally, act locally".

If we accept that sustainable development means "meeting the needs of the present without compromising the ability of future generations to meet their own needs", then its accomplishment depends and is influenced by almost every political, social, economic decision and/or administrative action which we take at present.

The analysis starts from the observation that at the end of the first decade of the XXI century, after a long, traumatic transition to pluralist democracy and market economy, Romania still has to overcome significant gaps compared to other Member States of the European Union, together with the adoption

and implementation of the sustainable development principles and practices in the context of globalization.

Despite progress in recent years is a fact that Romania still has an economy based on intensive use of resources, an administration and a civil society still in seek of a shared vision, and a natural capital facing the risk of damages that may become irreversible.

Technological shift in recent years has brought oil in the global energy industry forefront. The hydrocarbons can today be extracted from geological formations that could not have been accounted for as a resource a decade ago. Natural gas abundant on North American markets offers the manufacturing industry a cheap and clean form of energy with much lower carbon emissions than coal. International trade with liquefied natural gas (LNG) has increased significantly, which helps to break monopolies on regional markets, and to obtain better prices and contract conditions for consumers. Oil gives consumers the cheapest and most accessible unit of energy, which enables economic development and construction of reliable and clean high-tech energy systems.

At global level, coal is the main fuel for energy supply, and its price is low compared to other fuels. However, coal is the largest source of pollution in the production of electricity.

According to the EU documents, coal is only part of a diversified energy mix, contributing to the security of supply. The future of coal in Europe depends on the success of the 20/20/20 EU Program, and its rivalry with natural gas on the overall energy mix. While natural gas is threatened by the instability of prices, by the uncertain increase of reserves, and by the exploitation of unconventional resources, the development of technologies for carbon capture and storage, and other emerging clean technologies can enhance the role that coal can play in a secure and sustainable future.

The International Energy Agency scenarios is estimated that the EU energy mix will still be heavily based on fossil fuels, including coal, and for the countries of Central and Eastern Europe, coal will be the main pillar in energy security right up to 2035. Therefore, fossil fuel security and access to resources must remain a priority for the future energy policy of the EU.

Regarding coal, in EU documents this is only one component of a diversified energy portfolio, contributing to security of supply. Given the development of CCS (carbon capture and storage) and other emerging clean coal technologies can play an important role in a secure and sustainable future.

The 2050 Roadmap policy document whereby the European Union assumes de-carbonization policies (90% reduction in emissions by 2050 compared to 1990), is favored but switching to other types of fossil fuels and are encouraged new technologies: natural gas as a transitional solution on short term; renewable resources, on long term; requires increased energy efficiency; requires the development and implementation of new clean coal technology use.

Programmatic European documents tend to give unilateral concerns about emissions of greenhouse gases, neglecting other benefits of coal, always conditioning to keep it as a key resource for successful implementation of clean technologies (CO_2 storage, reducing SO_X and NO_X emissions), at reasonable costs.

2. Characteristics of sustainable development in the hydrocarbon extractive industry

Despite the fact that hydrocarbon extraction is achieved in a closed system, which should enable them to avoid or, at least, substantially reduce all forms of pollution, the exploration and exploitation of oil and gas deposits continue to be among the most polluting industrial activities.

Hence, in the extractive industries of oil and gas, the sources of pollution are numerous as negative effects of pollutants are serious and long lasting.

2.1. Oil

By the nature of its activities, OMV Petrom (2), the main oil producer, has a special responsibility for managing environmental impacts and ensuring safe and efficient operations. It aims to apply best practice environmental management, paying special attention to emissions of carbon dioxide, water resources and including natural gas, the cleanest fossil fuel, into the energy mix.

Oil, heavy oil, salt water and various chemicals contamination of land around drilling and extraction wells is, with all its incidentally character, extremely harmful to soil, surface water and groundwater. The severity of pollution will depend, of course, on the nature of the pollutant, its quantity and scope that the pollution occurs. Inventory of contaminated land in various degrees with oil, salt water or mixed blends indicates for the whole country an area of about 50,000 ha. Of these, about 5,800 ha are directly affected by nearly 12,000 productive wells in operation.

Preventing and combating pollution after it has come true can be done in many ways and it is achieved through complex actions often extremely expensive, especially in cases where pollution has already occurred. Of course, the best way to prevent pollution is to significantly reduce emissions (in air) and discharges (in water and soil) of pollutants from each of those sources for oil extraction industry. This reduction can be achieved by advanced technologies designed to reduce waste generation at source, recovery and reuse of waste, and the efficient use of technology regardless of their performance.

Under existing technology at extract oil rigs, ***prevention and combating the environmental contamination with specific pollutants*** can be carried efficiently out through a range of measures in order ***to comply with sustainable development requirements***:

- building a database that includes all sources of pollution in the investigated area, with identifiers, location, specific pollutants concentration/amount compared to their permissible limits etc.;
- continuous monitoring of extraction installations, storage facilities and all other potential sources, for rapid intervention in case of failures that cause pollutants emissions or discharges;
- regular inspections of installations (especially of pipes and connections) for the timely detection (preferably before production) of cracks and leaks imminent or those who have already occurred in order to remedy their operation;
- prevention, through specific technical means, of corrosion and abrasion of the surface and depth installations;
- enclosure arrangement of each well so as to avoid spilling out liquids that can escape the installations during oil extraction;
- salt water collection and underground reinjection to maintain or restore reservoir pressure;
- diminish or, if possible, avoid long distance transportation and reinjection of salt water in their areas closest to separating/collecting stations;
- efficient treatment of waste waters (resulting from boreholes, wells repair and cleaning of oil tanks) and their evacuation either by underground reinjection or by reuse in the extraction process after proper cleaning of oil substances immiscible with water etc.;
- avoid or considerably reduce seepage into the soil by clay waterproofing, PVC etc.;
- facilities dismantling and perimeters rehabilitation occupied by them, immediately after abandoning oil fields whose deposits have been exhausted;
- proper set up of new wells, taking into account the topography, hydrographic network, aquifer, soils, vegetation and fauna of the area in which they will operate.

In conclusion, OMV Petrom's operations to minimize the impact on the ecosystem, it undertook to manage resources sustainably. These efforts include efficient use of water, wastewater treatment and disposal in an appropriate way in areas with high biodiversity sensitivity, and prevention of harmful emissions.

2.2. Natural gas

Romgaz (3), the largest gas producer, conscious of its relationship to its dynamic business environment, society and the environment, has expanded, in time, its responsibility to shareholders and social media influenced by its work. The management assumes that the ***principles of market economy, people and the environment can be harmonized in a corporate strategy of sustainable development.***

Accepting the role that it has in its relation to the social expectations, Romgaz assume the social responsibility as a freely chosen corporate initiative beyond economic and legal obligations, in order to fulfill in the long term social commitments that contributes to community development and improving quality of life. In this regard, the company has a proactive attitude to continuously improve working conditions for employees, focusing on improving the quality and environmental performance, philanthropic and substantial sponsorship acts for areas such as education, culture and sports.

In its activities, Romgaz pursues an environmental policy focused on continuous improvement of environmental performance, pollution prevention and energy conservation climate. In order to achieve their strategic objectives and to implement the quality management system, Romgaz invests in:

- closed collecting systems of water reservoir during exploitation of productive wells;
- closed separating systems of water reservoir and gas wells on probation (discharge/pumping etc.), RK interventions;
- replacing/upgrading gas compressors in order to reduce electricity, gas, oils, technological waters consumption, noise/vibration;
- drying of natural gas with low energy and raw materials consumption;
- use of vehicles with low fuel consumption;
- eliminate waste from Romgaz exploitation activities, through their recovery;
- achieve the abandonment of gas wells and reuse of aside land affected;
- construction/upgrading of treatment plants for sewage and/or reuse these used waters in industrial and technological flow;
- construction of injection gas wells;
- eliminate all methane gas loss during transportation process;
- using pipes/valves of the highest quality in order to eliminate some current and capital repair costs;
- conducting studies on landslides field to prevent work accidents.

To comply with sustainable development requirements, Romgaz operates promoting actions and initiatives leading to saving resources, reduction and optimal management of specific waste, and reduce risk factors for the environment, continuously pursuing the improvement of efficiency of environmental protection, support for Romgaz managerial process, by:

- pollution prevention;
- implementing programs for environmental protection;
- maintenance and continuous improvement of environmental performance;
- regular analysis of environmental performance to monitor the progress registered by the company.

3. Characteristics of sustainable development in the coal mining industry

Coal is the most prevalent resource for energy production based on fossil fuels. The share of coal as an energy source has experienced significant growth due to its status of safe resource, widespread and its affordable price.

The mining activity produces multiple negative effects on the environment and various effects that persist after stopping of mining operation, involving damage, direct and indirect, which would be borne by the entire community for a long time. Although the severity of the negative impact depends on several factors (the size of area operations, technology used and measures taken to reduce impacts) they are inevitable to some extent.

Like many industrial activities, coal mining generates a series of negative impacts on the environment, the importance of which is closely related to the mining type that is practiced, geography and ecology of the area affected, and the public attitude on this issue. Many modern mining controversial aspects are that the extractive industries must deal with enormous volumes of waste.

In both cases, in underground mining and in quarrying, the operations take place in the vicinity of the extraction area. Damage features and the affected area can vary widely, as in one mine a variety of techniques used to solve these problems may occur. A general distinction can be made between the restoration, in which the land comes back to its original use and initial topography, and the recovery, which creates different uses and topography.

Underground mining produce several types of waste, including those from digging shafts and galleries for bringing to the surface of coal, materials from inside the deposit, and residues from waste treatment facilities. Currently, waste treatment issue is the need to treat old dumps, many of which are in an advanced state of deterioration. Moreover the visual impact produced by them occurs, many becoming structurally unstable due to moisture, especially those on steep slopes.

Exposure to moisture can cause emissions and chemical instability of mineral waste. Toxic emissions when oxidation components for producing acid compounds may be release, and there is a danger of being taken over by local waters. As a chemical reaction, heat may be produced from the combustion of coal particles that remain in the mineral waste. Storage under supervision, compacting, or treatment prevents spontaneous combustion. These methods help to re-vegetation, in many parts of the world being put back into production as agricultural land, especially.

In quarrying mining, stripping to obtain coal share is 25 to 1, this large volume of waste being usually returned to the excavations, when mining was completed. It causes degradation of the landscape and occupation of large areas for land pits, dumps, warehouses, industrial buildings and roadways, preventing land use for any other purpose. Similar problems are often encountered in landfills, producing disturbance of groundwater flows, toxic releases and other pollutants, erosion and crumbling of unstable slopes.

The best practice for land recovery is that stripping from excavations made recently and located near areas of operation, to be compacted, covered with fertile land and re-planted. This method requires financial support for a longer period, which entails high costs. The success of this method depends on many factors such as the acidity or alkalinity of the soil, the presence of moisture, the degree of ground compaction, temperature, presence of nutrients factors and necessary micro-organisms.

Less drastic but still significant is ***the impact of coal mining on other environmental factors,*** namely: ***water pollution, dust and noise pollution.***

To comply with sustainable development requirements, Clean Coal Technologies (CCT) applying can activate new coal resources that can be used in accordance with environmental objectives. Therefore, companies that extract coal operate promoting actions and initiatives leading to saving resources, reducing and optimal management of specific waste, and reducing environmental risk factors, while watching continually the enhancement of their environmental protection through:

- carbon capture and storage;
- obtaining clean coal combustibles: coal liquefaction, underground coal gasification (GSC), representing a growth potential of global coal reserves in an environmentally friendly manner.

4. Conclusions

It is widely accepted that the mining industry is a vital sector of a country where there do exist natural resources that can be exploited. Experts argue that this industry is a source of foreign income, foreign direct investment and, not least, is the main and sometimes sole provider of energy of a country. Activities in the extractive industry of any state provides employment to the population, rending contributions to the public budget through payment of taxes, as revenue from these activities may be directed to charity, but at the same time, there is an environmental risk, greater or less, directly linked to each initiative taking place in this industry.

Mining and quarrying activities are widely recognized as having a significant impact on the population, both in financial, and in social, cultural and environmental terms. More increasingly, in recent years has emphasized the need to minimize the negative impacts and to promote the positive elements that control negative externalities, and to equally develop the skills of those involved in minimizing undesirable impacts.

Entry of Romania into the European Union has imposed harmonization its policies with European policies in all areas, including towards sustainable development, both nationally and regionally. If in time, after 2001, various plans and alternatives to national development strategies were initiated and developed, reflected more or less correct in the "sustainable" realities around us, today we face some commands that will fundamentally influence Romania's future.

Although real progress in recent years have been done, is a well known fact that Romania's economy still relies on intensive consumption of resources, on a society and an administration still aiming to develop a shared vision, and on a natural capital affected by the risk of damages that may become irreversible.

Based on these considerations, ***the main objective of this work was to identify those coordinates of sustainable development policy applicable in the mining industry in Romania,*** so achieving these strategic objectives to ensure, in the medium and long term, high growth and, consequently, a significant reduction of social and economic disparities between Romania and other EU Member States.

In conclusion, for an adequate valorization of sustainable development opportunities in the extractive industry sectors analyzed, the demand on the domestic and international markets will have the decisive word, with its prices and circumstances fluctuations, with the chances they offer, but also with the threats they imply.

Efficient valorization of these opportunities and avoiding the potential threats depends ultimately on the ability of businesses to develop distinctive competencies and competitive advantages, in a word, to be able to face the increasing domestic and international market competition.

By appropriate industrial policy measures in the mining industry, the State can increase this capacity in industries where real competitive advantages and potential exist, as well as in industries showing a particular strategic interest.

Endnotes

(1) Romania is a republic in Southeast Europe, bordering the Black Sea, Bulgaria, Ukraine, Serbia, and Moldova. With 19.94 million inhabitants (2015 estimate), it is the seventh most populous member state of the European Union. Its capital and largest city, Bucharest, is the sixth largest city in the EU. It has been a member of NATO since 2004, and part of the European Union since 2007.

(2) OMV Petrom S.A. is a Romanian integrated oil company, the largest corporation in Romania and the largest oil and gas producer in Southeast Europe. It is a subsidiary of OMV.

In late 2004, Petrom was privatized by the Romanian state and sold to Austrian oil company OMV. As of 2005, it was the largest privatization deal in Romania's history.

(3) S.N.G.N. Romgaz S.A. (or simply Romgaz) is the largest natural gas producer in Romania and one of the largest in Eastern Europe. The company is responsible for producing around 40% of the total natural gas consumption in Romania. Its majority stockholder is the Government of Romania, which owns 70.01%. Fondul Proprietatea owns 14.99%, while the remaining 15% is owned by various shareholders.

Abstract

This paper deals with revealing the many factors that affect production and price trend in mining industry, the most important being fluctuations in profit rates, fluctuations in extraction cost and taxes introduced by the Government. Some, such as taxation and the profit, can be treated as variable pricing policy by the government to influence the extraction of non-renewable mineral resources. As often it had been discussed that market imperfections are "best friends of conservatism", the second part of this paper emphasizes that monopoly can exist in mining industry as in manufacturing industry, affecting depletion rates and thus the cost/price of fossil fuels and mining products.

Keywords: natural resources, mining industry, taxation and profit, price trend, cartel, market

Introduction

Profit level fluctuations may have strong effects on production and price trend in mining industry. At the same time, the charging system may have strong effects on the policies used in the mining industry. Operating with the basic economic principle is restricted by many real world constraints (Virmani, 1985).

For example, fluctuations in profit market rates; if it will increase, ceteris paribus, the extraction will increase, and conversely, if rates fall, then there will be a slowdown of mining extraction rhythm.

It is well known that the profit market rate may increase or decrease quite rapidly in a short time (Samuelson and Nordhaus, 1992). Therefore, the first objective of this research is to reveal this type of uncertainty, as it is always in the attention of resource owners when they set their depletion plan for their deposits.

Economic analysis of extractive industry is fundamentally different from the analysis of agriculture, manufacturing and services. The main reason is that the mineral resources are exhaustible resources. In other words, in mining industry an initial stock of reserves will exhaust in time. If we start from the premise that the owner of a resource, like any other owner, is seeking for maximum gain, then it must consider specific factors, unique in the mining industry (Home, 1979).

Hence, the second objective of this research is to examine the optimal level of extraction of non-renewable mineral resources in terms of government which wants to maximize social welfare by exploiting these resources.

1. Factors affecting the reserve depletion level

There are many factors that affect production and price trend in mining industry, the most important being: fluctuations in profit rates; fluctuations in extraction cost; taxes introduced by the Government. Some, such as taxation and the profit, can be treated as variable pricing policy by the government to influence the extraction of non-renewable mineral resources (Kula, 1994).

1.1. Changes in profit rate

Profit level fluctuations may have strong effects on production and price trend in mining industry. First suppose that the profit market rate increases. This means that the revenue rate obtained from an alternative investment project, say term cash deposits, increases. If owners do not undertake any changes of the originally conceived plan, the reserves stock will lead to achieving sub-optimal rates of income over time (Barnett, 1979).

The way to avoid these losses is to move production today. This means that the owners will extract and sell more now, which will lead to lower the price asked on the market. Therefore, less to extract, higher the net price of the remaining reserves may rise. This means that reserves would be exhausted in less time than it would increase profits.

Situation in Fig. 1 illustrates this situation. The curve “ab” is the production and price trend before increasing profit. Immediately after the increase, owners should make an adjustment by increasing production, and then prices start to fall at moment t(0) to the “a” level. For the remaining time left the owners will extract less so that the annuity/rent of the reserves left would grow at a higher rate. It will short depletion time from “T” to “T '”. The new production and price trend "a'b” will be steeper than the previous one "ab".

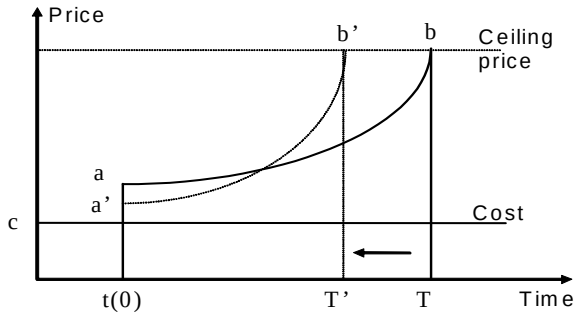

Fig 1: Effect of profit rate growth on production and price trend, and on deposits depletion time

If the profit rate falls, opposite phenomenon will occur. Original price will increase as owners push their production into the future by reducing current extraction. This is because lowering profit rates make stocks return more attractive than current production. This is obvious also in that a lower profit rate would show a lower growth trend than in the previous case. This means that depletion time increases, as shown in Fig. 2.

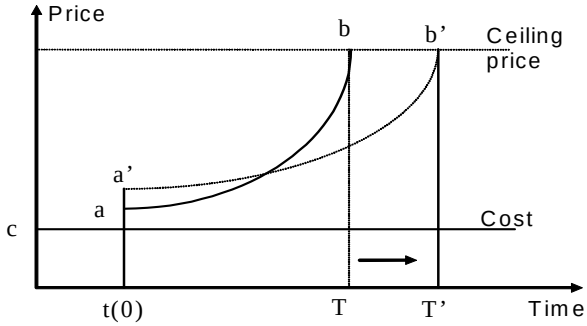

Fig 2:Effect of profit rate falling on production and price trend, and on deposits depletion time

1.2. Fluctuations in extraction cost

In the beginning let's assume that extraction cost increased. This can happen for a variety of reasons such as lack of skilled labor, wage growth in mining industry and basic resources decline as owners start extraction from fields with difficult access.

An increase in mining costs will reduce the current production level and therefore will increase the starting price, but will reduce further prices. This situation, in turn, will reduce the amount required in the near future and will increase the future quantity. The net effect will be the increased depletion time.

The situation is shown in Fig. 3. As the cost of extraction increases, the rent will be reduced. In response, the owners will reduce the current production and will increase, at moment t(0), the initial price "a" to the new price "a'", so the new production and price trend will be "a'b'".

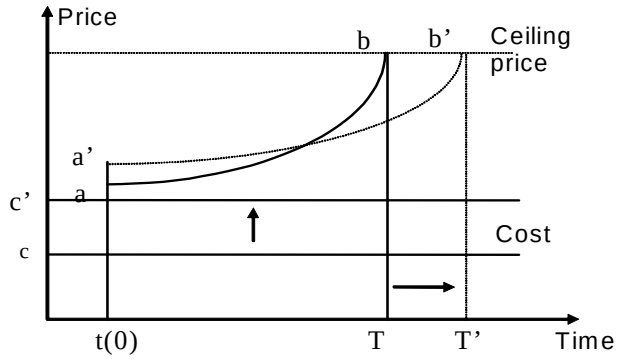

Fig 3: Effect of extraction cost on production and price trend, and on deposits depletion time

On the other hand, a decrease in the extraction cost will have the opposite effect, by increasing the initial value of the rent. If no adjustment is made, it could lead to a situation in which the cancellation price would be reached faster than desired, leaving owners with unsold stocks.

To avoid such a situation, the owners should lower the starting price. The gain will be that when extraction costs fall, the immediate production level increase, which in turn will reduce the initial price and depletion time (as seen in Fig. 4).

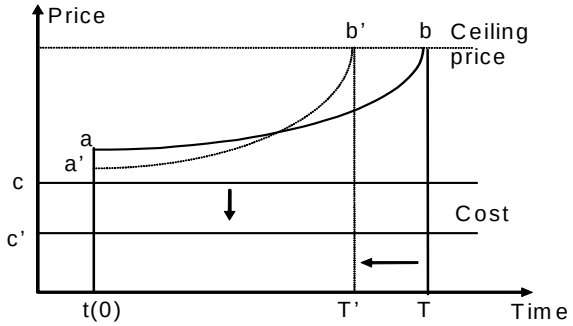

Fig 4: Effect of extraction cost lowering on production and price trend, and on deposits depletion time

1.3. The charging system

The charging system may have strong effects on the policies used in the mining industry. In this respect we can mention several charges.

1.3.1 Excises

Taxing the value of mining production will increase costs, which will have an effect similar to that shown in Fig. 3. For a mine owner, a tax on income is a cost that will reduce the current extraction and enhance deposits depletion time. Moreover, this type of charge will cause mining companies to postpone extraction so as to delay (or suspend) payment of taxes. Thus, they prefer to keep reserves in deposits, where there are no taxes to be paid (Kula, 1994).

1.3.2 Ad-valorem tax

This is a fixed tax on the price of each unit of production, usually a certain percentage of the value of extracted production. The effect of this tax is to reduce the deposits depletion rate and increase their depletion time. Therefore, there is a difference between the effects of ad-valorem tax and excise tax, that the depletion rate reduction is lower in the first taxing case.

Suppose that the owners are proposing to postpone payment of taxes by lowering the rates of extraction. Where ad-valorem tax is chargeable, one will observe that as sales prices are higher, taxes paid on these sales will therefore be higher. Hence, in case of ad-valorem tax, the depletion rate reduction is not preferably as compared to excises.

The difference between specific and ad-valorem taxes can significantly influence decisions in the mining industry. If the government feels that the country's natural resource reserves are depleting too quickly, then a strong measure as excise tax may appear appropriate for a moderated depleting reduction of deposits.

One form of an action with lower impact is the use of ad-valorem tax, as an alternative opposite to imposing through excise tax. This is the main reason due to which conservatives tend for excise tax in the mining industry.

1.3.3 Property Tax

This kind of tax will reduce the depletion time of deposits. From equation (1) inherently results that the stocks value on capital market is the present value of future net profits to be obtained by the extraction and sale of these stocks. This equilibrium value will increase in time at the level of profit market rate, thus providing incentives to owners to keep them.

$$\frac{\delta L}{\delta Q(t)} = [P(t) - C](1+\gamma)^{-t} - \lambda = 0 \quad (1)$$

where: L = Lagrange multiplier;
Q (t) = amount extracted at time t;
P (t) = resource price at time t;
C = cost of extraction, is constant;
γ = rate of return;
t = time, in years.

Ceteris paribus, an annual tax on the amount of resources will powerfully reduce this incentive because as the deposit is kept intact one more time, the greater the taxes to be paid on it. One way to avoid paying this tax on all future periods would be extracting as quickly as possible and investing money in areas where there is a charge similar to this.

2. Models for market structure

Often it had been discussed the fact that market imperfections, especially if highly monopoly, are "best friends of conservatism", says Hotelling (1931). Should be emphasized that monopoly can exist

in mining industry as in manufacturing industry, affecting depletion rates and thus the cost/price of fossil fuels and mining products.

In this sense, arises the question in what ways a monopolistic behavior may differ from a perfectly competitive behavior in the mining industry. It should be recalled again that the objective of any business is the same, that is extraction of resources in a manner which to maximize the present value of profits over time (Hartwick and Olewiler, 1986). When this happens, the market rate of return will be one of the determinants of firms both monopolistic, and perfectly competitive firms. This is inherent in the economic fundamental principle (Ricardo 1817).

First, suppose that a monopolist owner is the sole owner of a set stock that he can extract at zero cost. Market demand curve, the monopolist owner must cope with, remains stationary in time. His problem is to find an extraction scheme to bring maximum profits discounted over time until all original stock (inventory) is depleted over time. Its marginally income increase from two consecutive moments of time will be:

$$\frac{MR(t+1) - MR(t)}{MR(t)} = r \qquad (2)$$

that is the percentage change in marginal revenue equals the time rate of profit, "r", or:

$$MR(t)(1+r) = MR(t+1) \qquad (3)$$

meaning that in every moment of time monopolist owners' marginal revenue amounts to the market rate of return.

In Fig. 5 is represented the situation in which production in each moment of time met conditions in equation (3). In Fig. 5(a), an output level at time t, "Q_t", corresponds to the price level, "P_t". In the next period, t+1, price, and thus marginal revenue, must increase linearly with the market rate of profit, which may be obtained only by reducing production, namely $Q_{t+1} < Q_t$.

When marginal revenue is discounted to market rate of profit, it is the same in different time periods. Last unit of extracted production will produce the highest undiscounted marginal income, which corresponds to the price limit "p*".

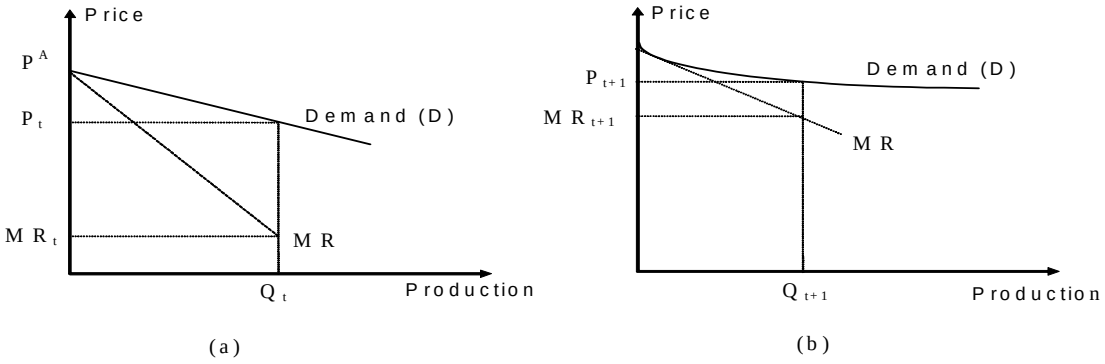

Fig 5: Stock depletion in monopolistic situation, with (a) time = t and (b) time = t+1

As the monopolist owner shifts upward the marginal revenue curve, traders that are competing on mining markets, very many on the market, will shift upward the demand curve every moment of time. In both market structures, the economic fundamental principle must meet the same profit rate. Since the marginal revenue curve is steeper than the demand curve, that is:

$$slopeMR > slopeD \qquad (10)$$

the monopolist owner will have to decrease production less than competing firms, each moment of time. Thus, the monopolist owner will use its reserves more slowly than firms existing on the competitive market.

Because the initial production of the monopolist owner is lower than those in competition, under the condition of two different price trends in both markets, then its initially price must be higher. Because marginal revenue is less than the price (see Fig. 6), monopolist price trend will be flatter than the competitive price, meaning that the price is growing more slowly.

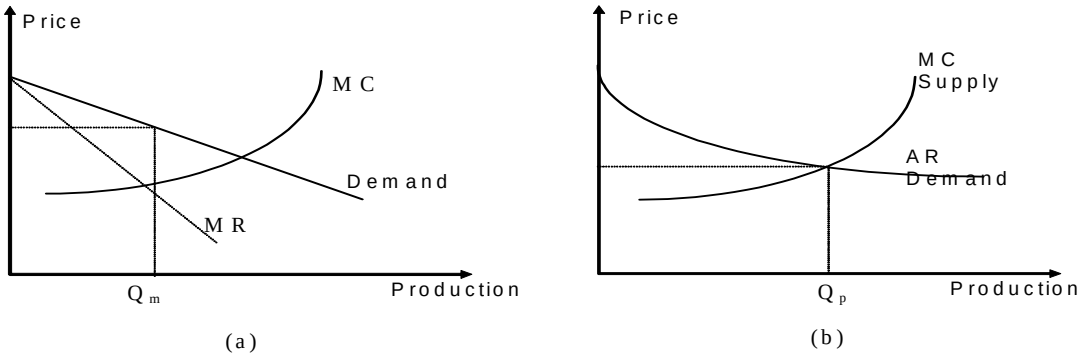

Fig 6: Price and production levels in manufacturing industry, with (a) monopoly and (b) perfect competition

This situation is shown in Fig. 7. In the monopolistic situation, the initial prices are higher, but their growth rate is lower. Assuming there is no change in demand for natural resources, then, in the monopolistic situation the reserve stocks will last for a longer time period compared to competition in the extractive industry.

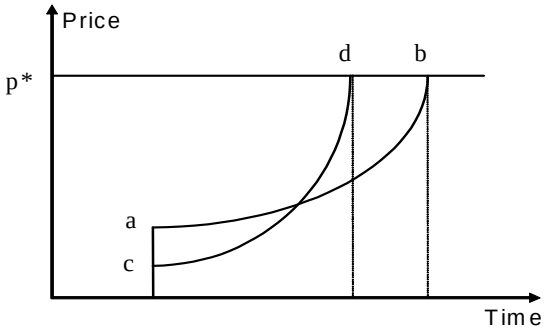

Fig 7: Price trend in the situation on (ab) monopolistic and (cd) competitive market

It was stressed that when depletion time (T) is long, then many changes can occur related to natural resource extraction technology and their use, which will affect the demand curve. It can be argued that as long as the competitive market prices are growing fast, this situation will encourage the users of these resources to seek new sources of alternative raw materials.

In a monopolistic situation, however, demand for natural resources, raw materials for manufacturing industry can not be avoided as long as their users are getting familiar to the slow growth of resource prices and thus will maintain their constant demand. With a constant demand, the ultimate depletion will take place in the competitive market, and if users gradually pass to substitutes, it is possible some of the stock of reserves to remain in deposits.

It is also inherent in our previous assertion that monopoly rent, which includes both the resource rent and excess profits, exceeds the resource rent obtained in the competitive market. It is therefore understandable why independent owners of natural resources are willing to form a cartel where they believe that may manifest as a collective monopoly (Pearce and Turner, 1990).

Indeed, a cartel is a group of independent owners who are trying, by common understanding, to act as a firm. In a cartel case, each owner agrees to produce less than would produce under competitive market conditions. The expected effect of the cartel is to increase the market price so that producers to earn excess profits.

In Fig. 8 are shown the production levels both in competitive market and in terms of a cartel. To simplify the calculations let's assume that we analyze the case of a zero rate of profit. Fig. 8(a) provides competitive price "$0P_p$" and production competition "$0Q_p$" by intersecting supply and demand curve. A competitive market firm believes the market price as given and produce at a level where price equals marginal cost, which then becomes the marginal revenue and schedules its own production at this level. Its market segment covers only part of its total sales.

Suppose now that to achieve excess profits all competing firms would join together to form a cartel. In this case, their production "0Q" would fall so that market prices are rising to "$0P_c$". Note that the ability to offer is not diminishing as production level reduces artificially. To each cartel firm is given such a share so that the reduced rate of production on the market can be maintained. Individual company depicted in Fig. 8(b) is told to reduce production at "$0Q_c$".

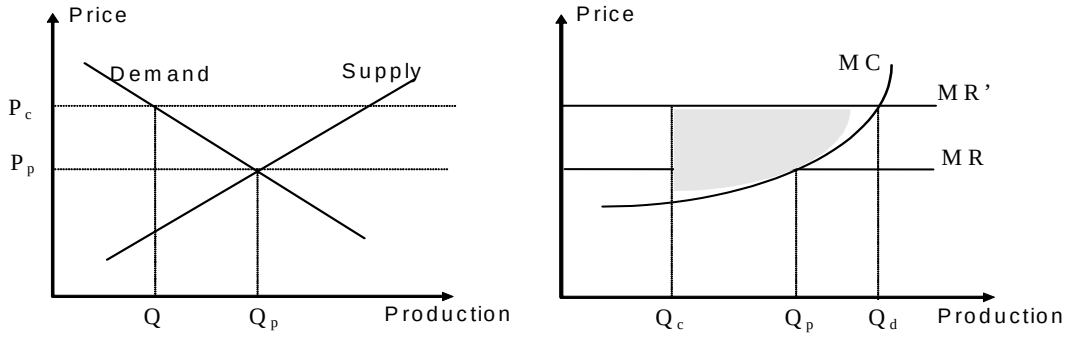

Fig 8: Incentives "to deceive" in terms of a cartel

In this new situation created there is a great temptation "to deceive". Individual company, by reducing its price just a little (slightly below the cartel price), may sell more, "$0Q_d$", at the same expenses as other members. For production "$0Q_d$", the firm's marginal cost equals the new marginal revenue, "MR'", and shaded area shows over-excess profit that can be achieved "through cheating" the cartel.

In fact, all firms are tempted to do likewise. If all are "cheating" the cartel, then market output will be much higher than pre-cartel level and therefore the price will be much lower. In other words, a cartel may also cause disasters to its members (Wannacott and Wannacott, 1986).

3. Conclusions

To conclude this analysis, we must point out that a cartel may increase prices only by reducing its production. However, at higher prices, members forming a cartel are tempted to produce even more than when the competitive market equilibrium. As the cartel situation has more success, the temptation "to deceive" will grow.

To be successful a cartel requires some measure of domestic policy group to ensure that each member takes care of its share. In natural resources depletion terms, in a cartel case, the amount extracted in

each moment of time will be less than in the competitive situation and therefore reserve stocks will longer remain in their deposits.

Economic analysis of extractive industry is fundamentally different from the analysis of agriculture, manufacturing and services. The main reason is that the mineral resources are exhaustible resources. In other words, in mining industry an initial stock of reserves will exhaust in time.

If we start from the premise that the owner of a resource, like any other owner, is seeking for maximum gain, then it must consider specific factors, unique in the mining industry. And such factors have been both identified and developed in this research. And this is both helpful and desirable for a sustainable development in mining industry.

Examining the Perceptions of Information Technology in an Elite Sporting Organization

Rene Leveaux, University of Technology, Sydney, Australia rene.leveaux@uts.edu.au

Abstract

In recent years, technology has enabled sporting organisations to become innovators in the global sports arena. Elite sporting teams and bodies are becoming increasingly dependant on technology for daily operations and subsequently these organisations are more and more reliant on technological developments in sport. Player training and management technologies and team performance tools have given sporting organizations the avenues to become more competitive. Organizations invest in information technology for many reasons, for example cutting costs, increase in production and services without increasing costs, improving the quality of services or products and sporting organizations and bodies are no different in looking to technology to gain competitive edges as well as improvement of athlete preparation. However, in spite of these innovations and the potential to gain competitive edges, some seem to struggle with technology resulting in an ambiguous and sometimes negative perceptions of IT services. This work examines the building of credibility in sporting organizations through education and the development of positive perceptions of information technology. The findings provide a basis for further studies and possible trials of differing education formats in technology to further develop both the positive acceptance of sports related technologies and assist in improving the sporting organization's environment.

Keywords: Credibility, Information Technology, Sport

1. Introduction

Organizations, including elite sporting organizations and clubs, operate in a strategic information technology (IT) environment, where the alignment of business and information strategies should be a significant focus for organisational effort. In organisations where the relationship between the IT function and the rest of the business is poor, this severely influences their ability to make the sort of contribution that the business demands (Ward and Peppard, 2002).

Iinformation systems and technology (IS&T) is possibly one of the more important developments in the commercial world over the past 50 years (Carr 2005) and this would similarly apply to the world of sport. Literature has many examples of organizations, including sporting organizations, who have obtained competitive advantage from their use of IS&T. However, in many organizations IT is seen as a cost (Kingsford et al 2003) and in sport the IT resources have been managed by staff in an environment where the potential for loss of knowledge is high due to staff turnover which may occur over short periods and where staff turnover is due to many reasons of which some are differing from the business norm.

If users are not willing to accept the information system, it will not bring full benefits to the organisation (Davis and Venkatesh, 1996). Whether IT is regarded as good or bad depends on how the users of IT perceive it and this perception may not necessarily depend on the technical quality of the systems provided to users. Thus, it is important to find out why users may have a negative manner perception of IS&T.

This exploratory paper reports on an attempt to improve the user perception of the IT function in an Australian sporting organization which has struggled to improve internal user satisfaction. Based on a snapshot of internal user satisfaction survey results and interviews, the paper presents a proposed method to enhance satisfaction and improve the users' perception of IT.

2. IT in the Organization

The IT function of a sporting organization is in somewhat of a quandary as to where it actually resides. Researchers over the last 30 years have put forward the idea of IT being a strategic asset and it being used strategically to further the organization's goals, and there is the perspective that to be competitive the organization would not survive without it. This additionally applies to elite sporting organizations and clubs.

Undeniably IT is the backbone of an organisation and its commercial dealings (Carr 2003): it has transformed business practices, can change the way business is conducted (Beheshti 2004) and in some instances organisations have survived based purely on their use of IT (Malik and Goyal 2003). However, IT is still seen primarily as an operational support function in many organizations (Beheshti 2004) with little emphasis placed on its importance to the organizations.

Though it may not be possible to quantify completely the value of the role of IT to an organisation, it seems imperative that appropriate investments are made in IT to maintain competitiveness. The perception of the "role of IT function in an organization" could have a direct impact on the effectiveness of development of IT capabilities (Ramakrishna and Lin, 1999). Avison et al. (1999) indicate that while IT can be critical to the organisation's ability to conduct and develop business, the IT function is often considered as a secondary activity. A by-product of this is that organisations may be reluctant to divert appropriate investment towards enhancing the IT function, and in sporting organizations and clubs is often the one area where investment is minimized.

IT usage appears to be one of the most significant phenomena to occur within sport in past two (2) decades. It may be used for general organizational functions including operational and managerial control, strategic planning and decision-making. However, the applications of IT have increasingly extended to various functions surrounding the preparation of the individual athlete and/or team.

Perception

Perception is based on the understanding one has of something or someone. It is an impression that a person has based on their understanding of another entity (be that a physical thing, a group such as a team or an organization or another person). Hence perception can be defined as "the process of making sense out of one's environment" (Daft 1997:p562) or "the process of selection, organization, and interpretation of stimuli from the environment" (Milton et al (1984: p22).

When looking at perception in a sporting organization or club, the impressions that a coach/athlete/support staff member has are no doubt influenced by their past experiences, as in any organization (Milton et al. 1984). As they acquire new information or their environment changes, no doubt their perceptions will also shift.

Negative Perception of IT

Negative perceptions of IT are misperceptions based on a lack of understanding or awareness (Overby, 2005a). Today an IT disruption can paralyze a company's ability to make its products, deliver its services and connect with its customers, not to mention foul its reputation, yet only a few companies have done a thorough job of identifying and tempering their vulnerabilities (Carr, 2003).

Reinertsen (2000) believes that no system is so fool proof that it can be operated by idiots, as a result he focuses his attention on the selection and training of people. This is an important concept for organisations and the negative perception of IT within the organisations. It appears to be human nature to act on perceptions, even though it may not be valid, so a negative view of IT can have disastrous consequences within organizations.

In any organization it is hard to change negative perceptions once they are instilled. Even by delivering projects successfully and ensuring IT deliverables, such as network uptime, are maintained

at optimum service levels, changing the mindset of end users within the organization may take considerable effort. Overby (2005a) believes it is impossible to improve how IT is perceived without basic competence in the function and some level of system implementation success. Simply being competent or achieving a major project win is not enough to change a poor perception.

Some consequences of a negative perception of IT within a sporting organization include missed opportunities for innovation and growth, inefficient IT operations, IT budget cuts, a decline in coaching staff / support staff / player morale, and user resistance to IT systems.

Credibility and Trust

Credibility and trust are two important elements that all should strive for in any sporting organization / club. A common misconception is that both credibility and trust are often thought to be same, but this is not the case as one party could have someone's trust but they may not be credible to others. Credibility as defined by Bashein & Markus (1997) is the standing someone gives to another as a result of a positive or negative action and it does not come from the credit we take for undertaking the action. Trust on the other hand requires one party to knowingly place themselves in a position where they may be at risk from or be vulnerable to another party (Brown et al 2004).

Psychology research has shown that a common affiliation leads to improved credibility. That is, in many situations people find others with similar thoughts and beliefs to be more credible than those with different thoughts and beliefs (Fogg and Tseng, 1999). Ignorance in the understanding of an organization's IT infrastructure leads to the formation of negative perceptions and poor credibility (Bashein & Markus 1997). As with industry, in a sporting organization it is important to determine how this low credibility has been attained and what can be done to improve the credibility of IT and change negative perceptions.

A common theme to build credibility is to manage expectations and not over promise. The credibility an IT function has within the organization, and the confidence the users (coaching staff, support staff and players) have in the competence of IT is based on past working experiences (Reich & Benbaset 2000, Huang & Qing 2007). Credibility can be easily damaged by a poor performance in the provided IT service. Once it has been lost, regaining credibility is difficult as restoring confidence may take considerable time and the IT function may continue to suffer for several years (Cormack et al 2001a, Horn Nord et al 2007). To ensure confidence in IT is retained, regular updates of achievements through the application of the organization's IT performance should be communicated throughout the organization. (Overby 2005a).

Trust also implies both parties will lower their own interests in order to achieve individual and joint goals. Once trust has been established through friendship, dedication, and a successful history of working together (Huang & Qing 2007) it will not necessarily be damaged by a poor performance and good performance will only reinforce the trust already gained and improve credibility. Conversely, if a member of the coaching or support staff or a player is not trusted, they will not be credible, regardless of their expertise and performance (Bashein & Markus 1997).

IT staff consult and communicate with all level in the coaching staff and player group in order to build a common awareness and create a positive organization/club-wide impression of the IT function. By partnering with the various stakeholders in the team(s) to tackle problems with shared knowledge and information, IT staff can seek further opportunities to add value across the entire organization. When partnerships are based on trust the joint effort will lead to enhanced outcomes (Barthelemy 2003) as most people 'value someone they have confidence in and can trust' (Bhardwaj 2007:p57). By doing this the IT function will be more focused, credibility and trust between the IT and the club and team's stakeholders will be increase and all entities will form a sound partnership(s).

3. Research Methodology

This exploratory work reports on the attempts by a sporting organization to improve the perception and acceptance of IT within their community – a semi-professional Australian sporting club competing in the premier level competition in their state. The IT function has struggled to over the years to gain meaningful acceptance and subsequently the uses and acceptances of IT dwindled rather than being further embraced.

The study was conducted through a discussion group, a series of interviews with a short survey and a case study. The advantage of doing a qualitative research was that it allowed greater understandings of the interviewees' personal constructs and experiences. All participants in the study were fully informed and voluntarily consented to their involvement. Participants were also free to withdraw from the research without giving reason or justifying their decision at any time, if they so wished.

The sporting organization was chosen due to the broad range of athletes competing at differing levels ranging from the social/weekend participant to individual full time athletes. The first grade / senior team had semi-professional and professional athletes on contract, of which some had additionally been recruited into the club.

The organization had various levels of successes and failures with the introduction of various information technologies ranging team and player management, match and player statistics to training and conditioning programs. The technologies used are stand alone in so much that they are not formal requirements of the club or mandatory to compete in the competition. There are some competition requirements where relevant match data and player statistical data is to be loaded to the competition management systems run externally by the competition management.

Interviews

A pre-interview discussion (n=2) was held prior to the commencement of the pre-season period in relation to the technologies in place in the club. As suggested by Patton (1990) this allows other related topics to emerge. From the discussions, a general interview script was developed based on issues derived from comments and points raised. All the participants were or had been involved in the club in either a coaching, team management or player roles for the previous season, and in the majority had been involved with the club for more than four years/seasons. McCracken (1998) discusses how interviews can draw on the past as well as the present to extract a deeper understanding of an issue than a simple survey type inquiry. Erlandson (1993) states that the use of semi-structured interviews allows the investigator to ask respondents for facts as well as gathering opinions. The same main format of questioning was employed in all interviews (n=11).

The interviewed subjects were solicited through chain sampling. Chain sampling "identifies cases of interest from people who know people who know people who are information-rich, that is, good examples for study, good interview subjects" (Patton, 1990) All of the 11 volunteers were chosen for interview on the basis of availability, suitable experience and use of technology(s) used in the club and in their chosen sport. Erlandson (1993) suggests that this technique of "purposive sampling" is preferred to random or representative sampling because the major concern of the researcher is to maximize discovery of the problem and the heterogeneous patterns that occur within the context of the particular study. Semi-structured interviews were conducted at a location that suited the interviewee and in general lasted on average approximately 20 to 25 minutes after which the interviewees were also asked to provide responses to a survey.

The focus of the interview questions centred on the views, if any, participants had to the uses of information technology and the impact of the use of the technology in relation to their individual or team preparation. Any views or opinions in relation to another sport, or technologies not employed by their sport, were disregarded. Their personal viewpoints on information technology, in relation to levels of application and introduction, what they enjoyed or did not enjoy with the use of the technology(s) employed in the sport, what opinions and frustrations they had with the information technology and IT staff and what aspects they had or had not appreciated. Participants were also

asked about their own adaptation to the use of the technologies, changes to their own practices leading up to, during and after a match were also explored. The interviews were recorded and transcribed for analysis. Follow-up phone calls were made to six respondents where clarification or further investigation was required.

A case study is an investigation of a contemporary phenomenon within its real-life context which provides rich contextual data obtained from an organizational setting and a single case study has the ability to increase our understanding of a particular situation (Yin 2003). It has been argued that a single case study, while not generalizable, has the ability to provide a valuable insight into a known context (Duhan et al 2001) and that the findings may be appropriate for someone in a similar circumstances (Cousin and Jenkins 2001).

3.1 The Field Site

The organization is being studied for the purpose of this study is a sporting organization with athletes competing at all levels from grassroots through to elite national players. The athletes compete in five open age teams and three Under 21 age teams. Each team consists of fifteen players and a group of reserve athletes. The teams compete in a state's premier competition. On completion of the state competition, the state team champion competes against the premier team from the other leading state in Australia to determine the national champion.

The organizational structures of each club in this competition and the sport, although slightly different, are in essence very much the same. The structure of the club in this study has a head coach with each team having one or two coaches and a team manager. A strength and conditioning team and medical and physiotherapy staff work with all teams and support the coaching staff. The organization has a structure with an operations manager overseeing the day-to-day running of the organization and reports to a board headed up by the organization's president. The IT staff are not directly linked to any specific team but provide IT support across all areas of the club. The overall team / player management is administered by the sporting organization's head coach.

3.2 The Problem

The organizational structure has a direct linkage to the problem as even though there is a head coach who oversees all teams and sets directions and processes for the season, individual coaches are not obligated to utilize the technologies, and in some instances, due to individual preferences, introduce their own preferred information technologies, only use a subset of the technologies or do not use the technologies at all. To some degree the individual team staff work fairly autonomously.

Similarly athletes, due to their own needs, are a mix of those using and relying on the information technologies or the feedback data provided to those who elect to not use the information technology due to various reasons.

When initiating a project requiring IT involvement, the head coach usually seeks an endorsement from the board and the technology is then introduced. It is then the responsibility of IT to implement and often manage the technology. There is very little consultation with either the other coaching staff, support staff or the IT staff.

There is very little education or hands on testing by the various end users. The coaching staff and athletes are provided with minimal information as to the functioning of the technology, and the requirements behind the introduction of the technology. The individual teams in the most only utilize the components of the system that directly affect their athletes or provide the relevant data required by the head coach. There is little knowledge within individual teams on how the other teams use the system. Once an information system has gone live, there is even lesser understanding within the club community of how the system holistically fits into the club's structures and processes.

This leads to frustration and eventually a negative perception of the system and IT in general. A single process within the club may involve multiple teams to complete the process. In not understanding the responsibilities of the other teams, users are open to unrealistic expectations of

what the system has to offer, and in some cases what is expected. When given the opportunity, the individual teams often set expectations of the technology without regards for the needs of the remainder of the club. These then become unachievable and the blame is laid on the assumed inadequacy of the system, and eventually adds to this negative perception of IT.

As a typical input from various units within the club, for example, coaching staff and medical staff and strength and conditioning staff, some of these units do not appear to fully understand the impact their own unit has on the structure of the club's processes. Systems are built incorporating the needs of all teams / athletes which is advantageous to IT staff as they are able to have a holistic understanding of the club's process. IT staff often appear to be more knowledgeable than individual units and users due to this holistic view of business processes.

3.3 Interviews and Surveys

Interviews were conducted during the preseason period (January / February) and followed by a survey. The survey was again conducted midway during the season proper. Interviews and the surveys were conducted at the completion of the season (September).

Figure 1 below is a summation of the three surveys. The survey taken in January/February was declared as baseline measurement from which improvements would be measured. Using the baseline measures, all team coaching staff agreed that a 5% increase in satisfaction of the baseline as an achievable target.

This comparison allows the perception of IT within the club to be gauged and the results show the users hold a poor or negative perception. The survey questions included communication skills, professionalism, understanding of the technology, culture of IT in the club, ability to recommend solutions, quality and timeliness of delivery, value to the club and individual teams and athletes, and overall satisfaction.

Team	Jan/Feb (Baseline)	Target 5% Increase on Baseline	Mid Season May	Septembe r	Sept. vs Jan/Feb (Target +5%)	
Team A	6.4	6.72	6.7	6.9	7.8%	□
Team B	7.1	7.45	7.0	6.6	-5.7%	□
Team C	6.0	6.3	6.1	5.9	-1.6%	□
Team D	6.8	7.14	5.9	6.3	-7.3%	□
Team E	6.5	6.83	6.2	5.8	-10.7%	□
Overall	**6.56**	**6.88**	**6.38**	**6.30**	**-3.9%**	

Figure 1: Comparison – May and September Quarters

4. A Framework for Improving Perception of IT within the Organization

While the overall results obtained in the September customer survey were somewhat expected the levels were of a surprise to the IT staff, the head coach, operations manager and the board. Given the perceived successful implementations of information technologies, it was anticipated that the results would have improved or at worst case remain the same. As such research was undertaken on how to improve the perception of the IT function and from the IT literature a six-step model proposed by

Peppard (2001) was identified. This model acts as a guide for studying the perception of IT. The six steps involve getting the basics right, enlisting key influencers, building credibility, seeking involvement early in projects, placing responsibility for IS with the organization (club) and cultivating and maintaining partnership.

Peppard (2001) suggests education plays a key role in this stage to impress upon business managers (the coaching staff) the process of value creation through IT and the key role that they play in this process. The issue at hand in the organization appears to be the lack of understanding of the holistic process that IT systems are built upon. It is important to understand that at this stage that the study focuses on the holistic education and its impact on perception of IT and not education on how IT systems work.

4.1 Getting the basics right

The first stage involves focusing on the IS function itself, ensuring that it can deliver basic IT services (Peppard, 2001). With this environment, while on a smaller scale, this involves basic IT functions such as network availability, support / help desk-like functions and reliability of applications.

Despite the improved use of project management and systems development tools and methodologies, the failure rate of IT projects is still very high. The biannual Standish group surveys continue to show high rates of IT projects that were cancelled before completion or are delivered over budget, behind schedule and with fewer features and functions than initially specified (Marchewka 2012). This is a disturbing statistic for IT departments eager to improve their perception of IT. Thus, it is important to get the basics of IT delivery and service to an acceptable level.

IT departments must make an extra effort to be proficient in project management, end user service and applications quality despite these being an organization wide responsibility. If this is not achieved it may be difficult for IT to meet the basic expectations of the business.

Within the sporting organization guidelines for achieving the basics are in place:

1 Due to the size of this environment, a near 24 x 7 on call support is necessary during the competitive season to ensure network availability, problem fixes, etc. are addressed within minimal timeframes. All outages are reported weekly to the operations manager and head coach.
2 For project management, a suitable methodology needs to be incorporated and adhered to be all stakeholders – coaching staff, support staff and athletes.
3 Good and timely service is a performance objective for IT staff. Review of end user satisfaction be conducted at key point during the year and playing season, to address any short comings and is taken in to account at end of season and staffing reviews.

4.2 Enlist key influencers

There are particular individuals within an organization who are pivotal to what happens and these individuals are the so-called opinion leaders or key influencers Peppard (2001).

Thus for IT transformation to occur it is important to get these influencers on board before proceeding as these individuals bring visibility to projects and add impetus to the process. However they can also decide the success or failure of an initiative. Key influencers also exist within the user community (club). These key users drive system change but may also have concerns regarding ease of use of the system or changes to job roles due to system implementation (Overby, 2005).

Jarvenpaa and Ives (1991) agree with Peppard and say that general managers need to be involved in information systems due to the magnitude of expenditure involved, the ability for IS to enable business initiatives such as business process re-engineering, total quality management, and the weight of evidence which demonstrates that when general managers are not involved in IS, investment is wasted on automating inefficient processes.

Key influencers are enlisted for the introduction of technologies and IT functions within this sporting organization. This is undertaken by ensuring that all projects are initiated and owned by the head coach. The head of the IT staff reports to the head coach and is constantly communicating with the other senior coaching and support staff. Weekly or fortnightly meetings are conducted to ensure that only items that are of high priority are being worked on.

4.3 Build Credibility

In establishing credibility it is important to bear in mind that credibility is not something that is taken, but rather something that is given; in essence it must be earned by and is derived from achievements and actual results (Peppard, 2000).

It has been suggested by Overby (2005b) that IT staff regularly present IT efforts and achievements to the board, the executive committee, other governing bodies and potentially the whole organization. This includes not only project work but also major maintenance and enhancement efforts, as well as successful results through the applications of technology.

To achieve success, a sense of trust and commitment, credibility must be developed between various participants to ensure a free exchange of beliefs and opinions. When credibility is lost it is difficult to regain as once a user perceives that someone or something lacks credibility, then they are likely to stop using the service or resource, hence providing no opportunity to regain credibility. Peppard (2001) says that education showing the value through the use of the technology, and IT and the key role it plays in this process, is important.

An important concept for building credibility is to manage expectations and not over promise as users have more faith in what IT has to offer if IT delivers what it promised. Often this is a difficult concept for IT staff as users can be unrealistic in their demands and has to be managed.

Within the sporting organization there appears to be adequate communication to users indicating value of the technologies and IT. Relationship between IT staff and team management provides the ability for dialogue due to the less formal organizational structures between IT staff and team management; and with the IT staff having a contributing factor in the team decision making processes.

4.4 Seek involvement early in the implementation of technologies

According to Peppard (2001) the IT function should actively seek out the involvement of the team stakeholders in IS projects and be willing to get involved in projects when invited by the stakeholders. From a project management perspective Marchewka (2012) suggests it is important to identify stakeholders as early as possible to enable adequate communication channels to be set up at the start of a project. This also encourages the users to take responsibility for the project. The outcomes are more accurate when the stakeholders/team staff is responsible for the projects.

When users (coaching staff and athletes) and stakeholders are involved early in projects there is less chance of missing important information or requirements about the desired way the system operates in their environment. This also enables athletes and coaching staff to think about the testing process and minimalizes any potential frustrations when the system is implemented.

In this organization this process is working fairly well. The introduction of any technologies, whether they are IT related or team related has to be initiated and approved by the head coach and board. The project methodology ensures that the initiators of any technology related project(s) to the organization and the IT staff work closely where enforced signoff is required. Often the sign off process is a point of frustration for the coaching staff as they feel that it delays the process but once they recognize the value it adds to the outcome they comply with the process.

4.5 Place responsibility for IS with the business

Peppard (2001), highlights the importance of business managers taking responsibility for aspects of IT that traditionally may have been delegated to the IT function and in this environment the senior team management need to take greater responsibility in the applications of technology.

There may be resentment in the taking on this responsibility as technology is foreign to them. However they must realize they are making decisions that involve using technology rather than pure technical or technology decisions. This implies senior team management may need to be educated on how to make these decisions which involve technology; however they must take ownership for these decisions which also infers taking responsibility for their component of IT (including all new and existing technology and systems).

Commitment is considered essential for the success of the system. Overby (2005b) notes that in order to change perception, IT staff must have a sponsor who share ownership and accountability with IT for IT and introduced technology.

In this sporting organization all technologies and IT systems have a "business" owner – usually the head coach. Any changes made to existing or new systems have to be signed off by the head coach and endorsed by the board.

4.6 Cultivate and maintain partnership

Peppard (2001) infers there is a possible danger of management becoming complacent and not recognizing their contribution to IT success.

Despite strong management commitment and detailed planning, an IT project may fail simply because IT personnel and users are unable to effectively handle their day-to-day interactions. Quality interaction, by way of communication and information exchange is considered a key success factor in IS development effort (Marchewka 2012).

IT departments must change their focus from a task-oriented method to a role-oriented method that emphasizes the relationship between IT and users of the technologies. Overby (2005b) says that IT departments should employ internal relationship managers to work with the business units to build relationships and/or partnerships and hence set the foundation to improve perception.

Within the sporting organization close relationships between IT staff and the senior coaching staff are visible at the higher management levels. The IT staff reports to the head coach and has a close relationship with other coaching staffs. However, the level of the relationships may not be noticeable at the lower end team staff and players.

5. Response to negative perception

It appears that the sporting organization is following most of the recommendations given by Peppard (2001 in the six step framework. So why does this negative perception towards IT exist?

For sporting organizations to be competitive, it is important that they invest in addressing problems concerning their technology and IT functions. A negative perception of IT may not necessarily be a problem of the technology / IT staff as it could be related to stakeholders using the technology without a complete knowledge of the how IT systems impact holistic process within the sporting organization.

Ward and Peppard (2002) believe Peppard's six-step process provides the possibility of improving the perception of IT through educating users. An education program could address the mindset blockages and thereby improving the perception of IT within the organization. According to Peppard (2001), education plays a key role to impress team management the process of value creation through IT and the key role that they play in this process.

Other literature supports the notion of education and training being used as a means to improve the view users have of the IT function. Olfman et al. (2003) believe education and training is a strategic necessity for staying competitive and delivering results. IT training literature shows that traditionally IT training has been to impart skills in the use of the particular systems to users. Olfman et al. (2003) indicate that IT skills training are typically built to illustrate the semantics of the system functions. Training is focused on 'what' the system can do and not 'why' it does what it does.

There appears to be little focus on how the system covers a holistic business process and adds value to the organization. By neglecting this aspect of the value of a system, there is little business

ownership. In their study on organizational learning strategies, Olfman et al. (2003) suggest that there is little business focus in terms of application of IT skill to business process and understanding what these skills and systems will do for the individual and the organization. They emphasise that the capability to focus on the larger business picture requires that IT skills training be considered in an integrative manner with organizational strategies.

In an era where sporting organizations are increasingly dependent on IT for value and gaining competitive edges, it seems remarkable that there is limited focus on this topic within sporting organizations. IT training must focus on the organizational needs not just how to use the system. End users must understand the holistic process and how IT assists them in achieving their individual and team goals.

Ewusi-Mensah and Przasnyski (1991) indicated that 30% of the executives who responded to their survey on information system abandonment indicated end users experienced uncertainty about an information system's impact on their job. This may lead to a negative perception of what IT has to offer and eventuate in abandonment of the technology that may have benefit to the organization.

According to Sein et al. (1996), training methods and approaches have focused most exclusively on ensuring that a trainee acquire the skills to use an IT tool and in a specific domain but with the advent and increasing use of technologies and IT solutions this narrow view of training will prove to be inadequate in preparing sporting organizations, teams and athletes of the future. They recommend it is important to incorporate a conceptual level of training, which refers to viewing the tool in the context of the entire system and the organization.

On reviewing the available it appears that training of the user in the holistic process and goals may be an important step in improving the perception of IT.

6. Conclusion and Future Research

There is reduced understanding of IT value and IT departments/staff are stumbling to facilitate the organizations demands for return on IT value which also applies to sporting organizations and elite level clubs. Organizations that fail to value IT and take on the benefits of IT will miss opportunities for innovation and possibly spend IT expenditure inefficiently. Thus many have taken up the challenge of recommending potential solutions to improve the value of IT. This cannot be done just by reducing expenditure on IT solutions as these solutions give organizations the ability to be innovators and have the potential to gain competitive edges.

The challenge for IT staff in a sporting organization is to enable the organization to see value and benefits in IT and technology and hence improve the perception of IT. Through this work, it appears this may be possible by improving the educational methods of end user training within the organization. This may be done by introducing holistic process training along with IT systems training.

This study is significant because it examines how a sporting organization can take advantage of IT. By formulating a strategic learning module for end users, it can assist the organization to stay competitive, provide a better training and match preparation environment for teams and athletes, achieve better results and potentially deliver an attractive environment to attract other athletes to the club/sporting organization. By understanding the value of IT, the sporting organization may be able to service their coaching and support staff and athletes more effectively. The findings could also be applied to other organizations that may be faced with a similar negative perception of IT or potentially where the IT department is viewed poorly.

Research Concerning the Usage and Concentration of Community Funding For the Fishing Sector on Financing Axis 4

Silvius Stanciu, Dunărea de Jos University of Galati, Romania, sstanciu @ugal.ro

Cezar Ionut Bichescu, Dunărea de Jos University of Galati, Romania, cbichescu@ugal.ro

Abstract

Developing support actions for complementary fishing activities can reduce the pressure on natural resources available within the community. Implementing eligible projects within Axis 4 of the European Fisheries Fund can ensure a sustainable development of the fishing sector, a rational exploitation of the fish resources and additional income for the fishermen community in targeted areas. The article proposes an analysis of the accessing of funds designed for the Sustainable development of fishing areas, while identifying the degree of concentration of the funds and projects implemented on this axis. Following the analysis obtained as a result of applying the Gini Struck methodology, a high level of concentration of funds attracted on Axis 4 has been identified, as well as governmental support funds and number of financed projects. The research represents an original modality to analyse the development of the fishing sector in the context of accessing community funds, useful for the business environment and the population in fishing areas because it can be a model for the future development of EMFF 2014-2020.

Keywords: EFF, Axis 4, Gini Struck, market concentration,

Introduction

The sustainable development of the fishing sector represents a priority for the European Union EU. Fish-based products have rich nutritious value, fish proteins being registered in the first value class from the point of view of chemical composition, with a balanced concentration of essential amino-acids, adapted to human organism. The increase in consumption of fish-based products is a way to ensure the security of alimentation at a global level. According to the Food and Agriculture Organization of the United Nations FAO (2001-2016) data, over 75% of the fish farming worldwide is used for direct human consumption. Fish-based products, which cannot be used for human alimentation, representing around 33 million tons annually, are sold under the form of forage (fish oil or flour), destined to feed poultry, pigs or carnivorous aquatic species. An analysis of Community funds for fisheries is performed by Stanciu (2014), which shows the sector's importance for Romania. Neculita and Moga (2014) analysed the EFF situation in Central and Eastern European countries under the influence of EU funds for agriculture and fisheries, by calculating the Herfindahl–Hirschman Index.

Materials and Methods

Information concerning the development of the fishing sector in the community has been gathered from the European Commission concerning European Fisheries Fund, of the CBI Market, of the Ministry of Agriculture and Rural Development of Romania, or from the statistic data basis of Eurostat, FAO Stat, and International Trade Centre. The EFF Programme (2007-2014) was under analysis, with a focus on the last five years. Gathered data has been statistically processed, graphically represented and interpreted. The results have been compared with those from specialty literature for an adequate interpretation.

Short analysis for the trade with fish-based products in the community

Supporting the fish farming sector in the community represents a way to reduce the dependence of the European Union market from imports, by developing the development of a sustainable fish culture, and a good management of natural resources. The European Commission Data (2014) show that the community market is the biggest importer of fishing and fish farming products in the world, with a percentage between 35 and 38% of the total products marketed worldwide. The exports of Member States represent an average of 22 % of global exports (figure 1). Self-sufficiency, represented by the report between the EU production and the total apparent consumption has been evaluated, for the year 2011, at approximately 45%.

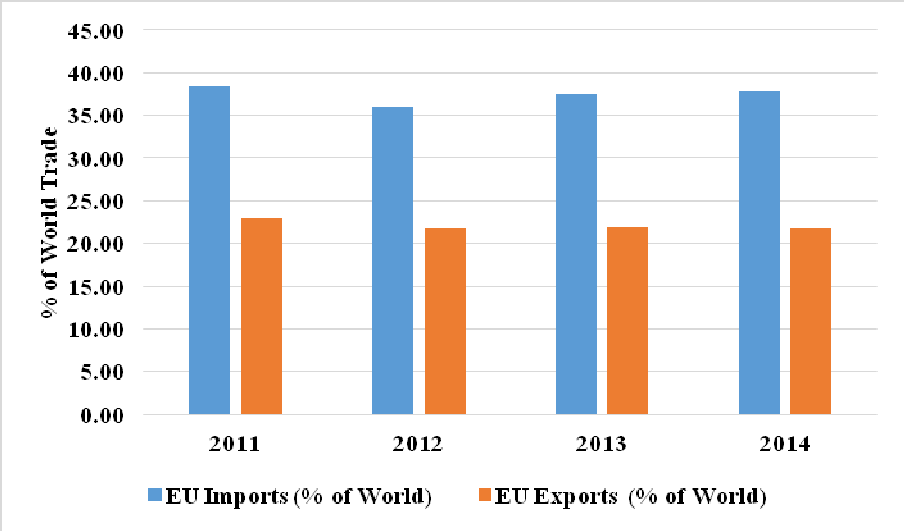

Figure 1: EU trade of aquatic products (% of World Trade)
Source (Author, using the ITC data, 2016)

Even though in the last period progress has been registered, as a consequence of the support given to the fishing sector, the commercial balance of the EU continues to be unbalanced. According to International Trade Centre ITC (2016), the commercial balance of the European Union in the transactions with fish products shows a significant dependency on extra-community imports.

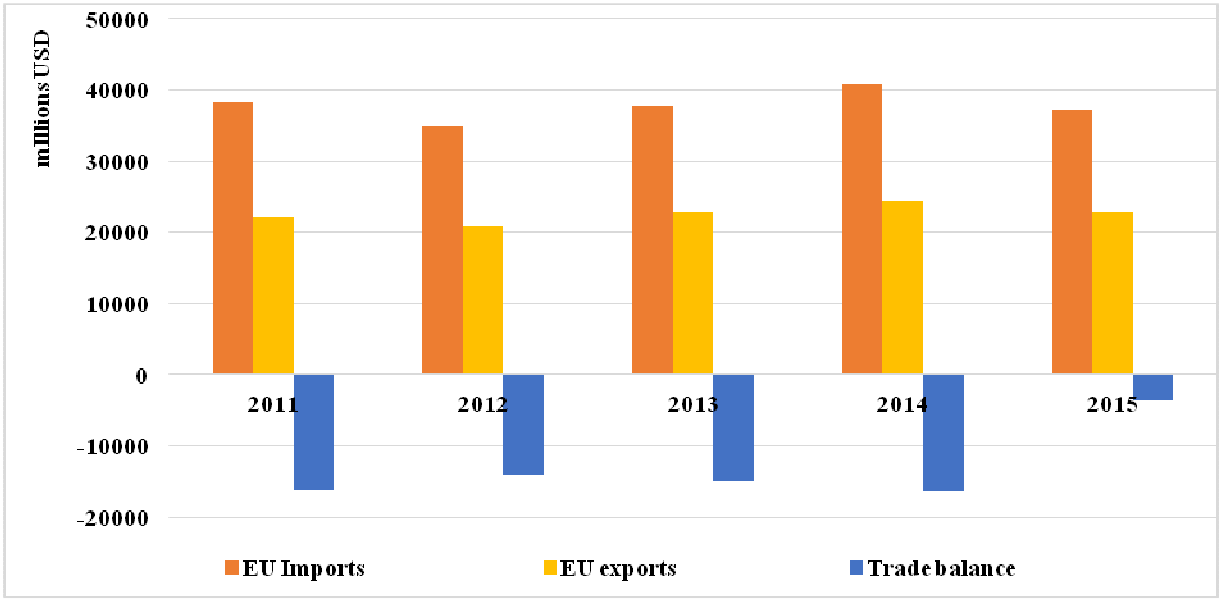

Figure 2: Community balance in the trade with aquatic products (Code 03 ITC)
(Source Author, using the ITC data, 2016)

Community measures to support fishing and fishing-related activities

In order to increase competitiveness in the community sector, to protect resources and reduce dependency of the community on imported fish products 4,5 billion euro have been allocated to member states, through the European Fisheries Fund, which began to be operational from the 1st of January 2007. The European Fisheries Fund (EFF)'s goal is to contribute to la realizing the Common Fisheries Policy (CFP) objectives, which specifically consist of ensuring the conservation and sustainable use of marine resources.

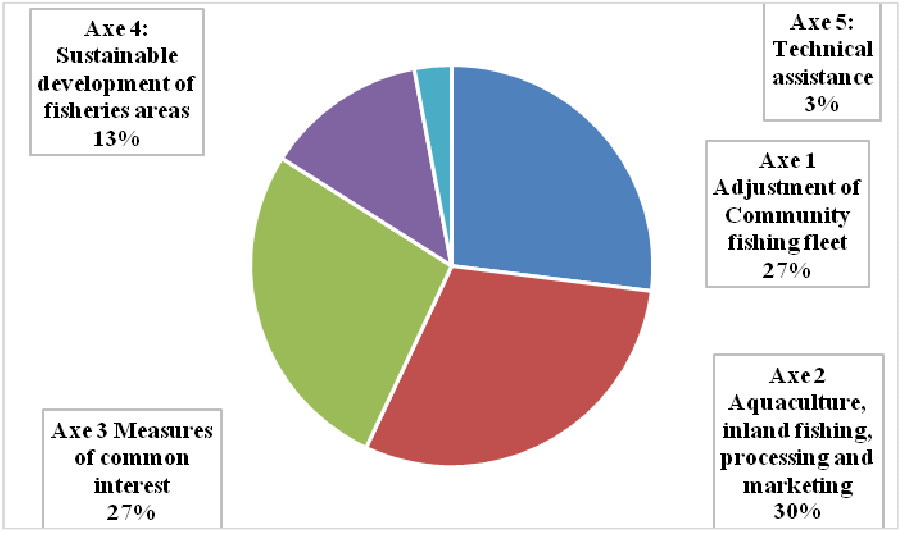

Figure 3: EFF Distribution on the five main axis
(Source Author, using Tokarski data, 2015)

The EFF provided for five priorities: measures to adapt the EU fishing fleet; aquaculture, inland fishing, processing and marketing; collective action; sustainable development of fishing areas; technical assistance to implement Council Regulation (EC) No 1198/2006. The distribution of community funds on the 5 axis show a relatively uniform distribution on Axis 1, 2 and 3 and reduced ratios on 4 and 5 (figure 3).

Analysis of accessing community funds on financing Axis 4 EFF

Funding on Axis 4 (Sustainable development of fisheries areas) is based on local development strategies, reflecting a bottom-up approach. The crucial difference between Axis 4 and other measures in 2007-2013 periods of the EFF was not so much in the contents of the actions. In fact, many of the actions carried out in Axis 4 were probably similar to those implemented under previous programs like PESCA, INTERREG, and EQUAL. The main added-value of axis 4 lies in the way in which these actions are implemented and linked together, both in and by, fishing communities themselves.

Almost 560 million euro has been allocated to help local communities reduce their economic dependency on fish catches. Coastal communities, and those near lakes and ponds with a significant level of employment in the fisheries sector, are eligible for EU aid to strengthen their general competitiveness, add value to fisheries products, develop tourism infrastructure and services, protect the environment, and encourage interregional and transnational cooperation.

Promoting priority Axis 4 concerning sustainable development of fishing areas through the European Fishing Fund (FEP) has been determined by the complex changes which affect the fishing sector and by the challenges with which the fishing communities are confronted at the level of the European Union (EU). The main objective of the Priority Axis 4 is the durable development of the fishing areas in order to minimize the decline of the fishing sector and to support the reconversion of the areas affected by the changes in this sector. Axis 4 completes the short term measures of the Common Fishing Policy (CFP) by economic, social and environmental support measures which fight against the exhaustion of fish stock.

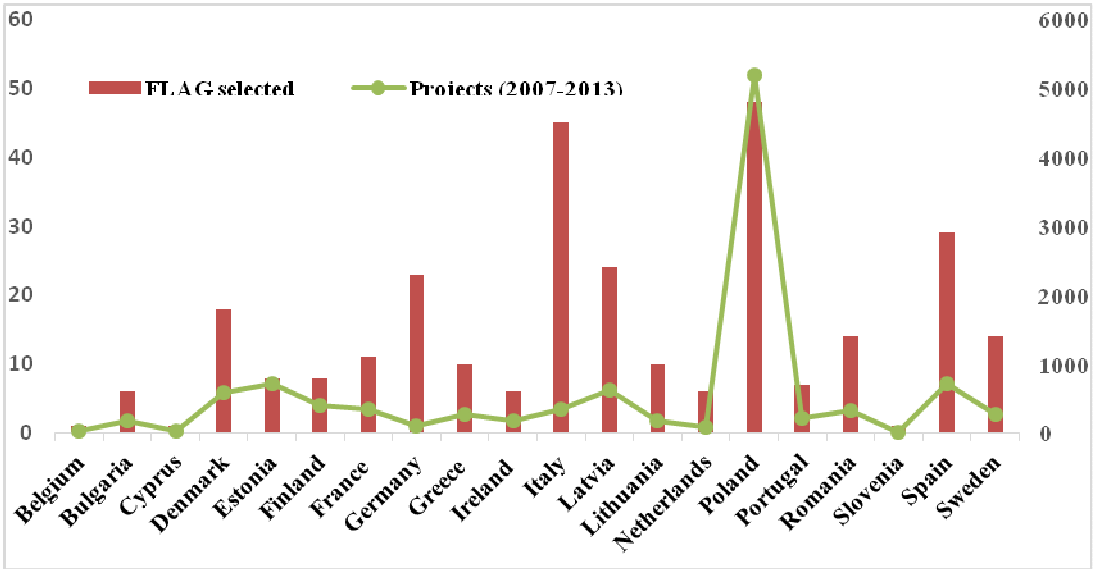

Figure 4: Number of FLAGs and projects implemented on Axis 4 in the community
(Source Author, using European Commission Data, 2015)

The implementing of Axis 4 has been made by the direct implication of relevant actors in well-established fishing areas, associated in Local Action Groups for Fishing (FLAGs) by elaborating and

applying a strategy of durable development, in conformity with the needs of the specific area. At the level of the EU 28, the implementing of measures of Axis 4 has been done through 312 FLAGs, selected, which have implemented until 2015 approximately 11316 projects, localized in 21 member states (figure 4).

The number of FLAGs per member state is between one unit, in Slovenia and 48 groups in Poland, country which detaches itself in the community, with a number of 5200 proposed and implemented projects, with a total value of over 319 million euro. Romania, with 14 local action groups and 322 implemented projects, with a total value of around 66 million euro, occupies modest positions in the community. Poland is the country which has allocated the biggest percentage to Axis 4, with over 45% of the total community funds destined to the fishing sector.

The geographical surfaces and the number of inhabitants which have benefited from the implementation of the measures of Axis 4 are represented in figure 6. Almost 5% of the total EU population, distributed on 14 % of the total surface of community states which have applied the measures of Axis 4 are represented by eligible population segments for proposed measurements.
The percentages of population and areas allocated by member state for the projects of Axis 4 are different, varying between 1, 2 and 49 % for surfaces, respectively between 2 and 62% for the inhabitants in target groups. (Figure 5).

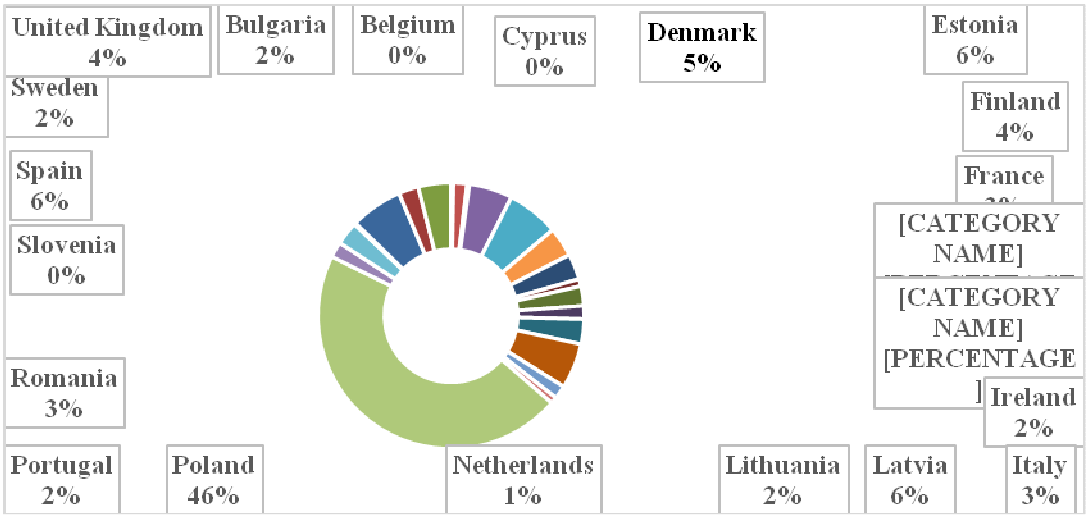

Figure 5:Precentage of funds allocated in Axis 4 from the total of EFF, by Member State

(Source Author, using European Commission Data, 2014)

In absolute values, Poland is the state with the most citizens within the eligible target segment, with over 3,5 million inhabitants, cu followed by Spain with 3,4 million, Germany with over 2,8 million inhabitants within eligible area.

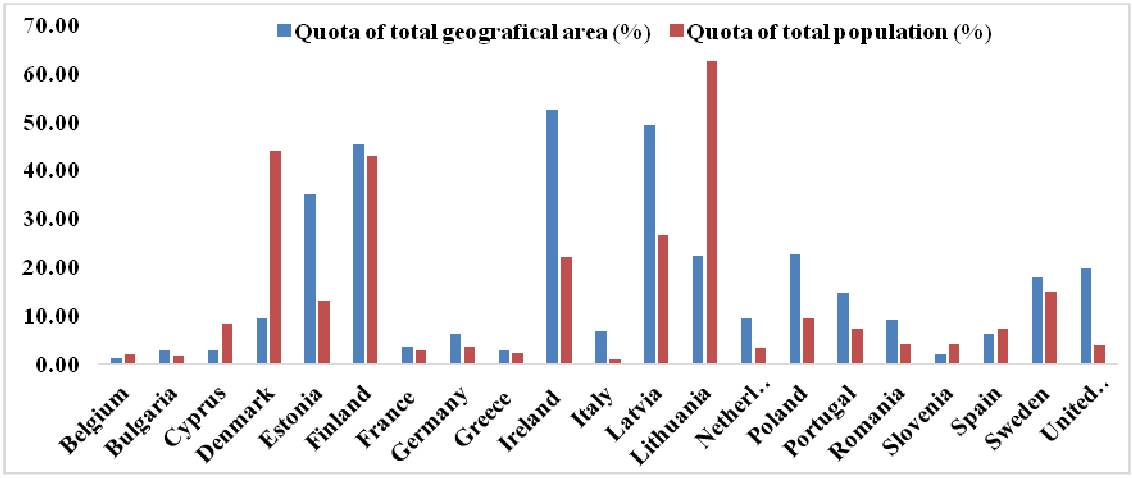

Figure 6:Population quotas and geographical areas which benefit from the projects of Axis 4
(Source Author, using CE data 2015)

Regarding implementation surfaces of the projects, included in the zones of FLAGs, Finland, Spain and Poland are the European States which have allocated the most important fishing areas for complementary measures for fishing. (Figure 7)

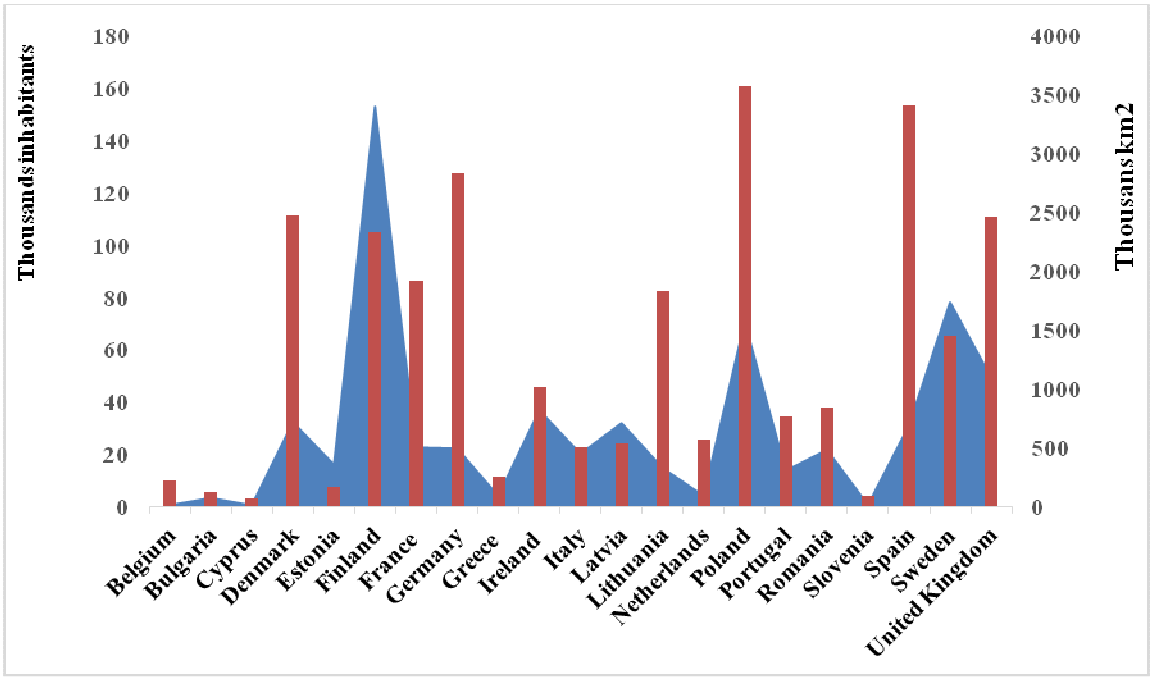

Figure 7: Surfaces and number of inhabitants in the eligible areas for proposed Axis 4 projects, by country
(Source Author, using European Commission Data, 2014)

The concentration of the projects, respectively of the European funds attracted by Financing Measure of Axis 4, in the community can be analyzed through the Gini Struck indicator.

Systemized data concerning the percentage of the projects, of the FLAGs crated, of the funds accessed and of the involved population in the implementing of the measures of Axis 4 are presented in table 1, Appendix. The calculation of the Gini Struck concentration coefficient has been realized based on methodology proposed by Săvoiu, Crăciuneanu and Țaicu (2010), according to the mathematical calculation (1)

$$GS=\sqrt{\frac{n\sum g_i^2-1}{n-1}} \quad (1)$$

Where n – number of member states which have implemented projects on Axis 4

g_i– the share of the analyzed variable

The results of mathematical calculations concerning the value of the Gini Struck coefficient, realized based on formula 1 and data in tables 2 and 3 and 4(presented in the appendix), under the form of the concentration degree of community funds , of the projects and local action groups constructed, of the population and geographical surfaces covered by FLAGs are presented in table 1. The total value of community funds allocated to Axis 4 has been taken into account for the 21member states analyzed (547785006.6 euro), the total number of local groups constructed (312), total number of financed projects (11316), total eligible population (27427311 inhabitants), respectively the surfaces allocated to FLAGs in the community (622533.899 km^2), according to CE EFF data . In the case of British states the conversions from SI measure units has been made. Where data concerning the projects, the population or the surface has not been presented, the FLAGs have been considered not to function and a null value has been considered.

Table 1:The value of the coefficient GS for the analyzed variables

Analyzed variable	FLAGs	FLAGs Projects	EFF (euro)	National Funding (euro)	FLAGs Area (km^2)	FLAGs Population (inhabitants)
GS coefficient value	29,53	49.47	47.39	52.11	34.35	29.56
Concentration degree	medium	high	high	high	medium	medium

Source Author, using own research

The data presented in table 1 show a medium degree of concentration of the population, of the eligible areas and of local groups constructed for the implementation of the measures of Axis 4 and a high degree of concentration for accessing community funds, correlated with governmental support and with the number of financed projects for the 21 member states in which projects have been implemented to support complementary fishing activities. An important part in concentrating attracted community funds is owned by Poland, which through its FLAGs has succeeded to implement 5200 projects, with a total value of (EFF and National Funding) 313212832 euro, with a governmental support of just 25%, visibly inferior compared to other member states. Poland is also the country with the biggest EEF allocation quota on Axis 4, covering over 40% of the total community allocations in this field.

Conclusions

Attracting non-refundable community funds in the fishing domain represents a competition advantage for member states regarding security of alimentation, a possibility to support fishermen communities to develop complementary activities to fishing and the sustainable development of the fishing sector. The analysis demonstrates the existence of a high concentration level for EFF allocated to Axis 4 in the community, correlated to the number of projects deposed and with the support allocated by governmental organisms. The dimension of the population in the target group, the eligible surfaces, close to fishing areas or the number of local groups constructed in order to implement the complementary measures for the fishing sector are at a medium concentration level in the community. There is no correlation between the size of the population and the eligible surfaces and the volume of EFF funds attracted. The analysis made can be taken as a positive business example for

the local communities and fishermen population or the by the governments of the member states concerning the accessing of non-refundable community funds in the perspective of the new EMFF 2014-2020 program.

Abstract

The success of manufacturing companies depends largely on how they are able to convert their human capital, it means the knowledge, skills and experience of the people, to the quality of the product or service required by the market. On that basis of that, the human capital is nowadays considered as one of the greatest competitive advantages. One of the goals of the company should therefore be the development of human resources. It means developing knowledge and skills of employees, increasing their performance, support for creative thinking and last but not least, the support of staff in further development. This article deals with the effective transfer of knowledge principle and explanation of the principles of lean manufacturing through a managerial game.

Introduction

More broadly used term management games is often used as a support of employees´ development in lean manufacturing. It means the games in a simulated environment that examine or, conversely, deepen knowledge of the players (employees). The advantage of these games is that they offer a safe environment without risk penalty. And thus they support creative thinking and attempts to solve problems proactively. [8]

Lean manufacturing is a production philosophy which may be associated with the industrial initiative of Henry Ford, which aims to produce as efficiently as possible exactly according to customer requirements. It aims to achieve the elimination of resources waste such as waiting, overproduction, unnecessary operations or movements. It focuses only on the processes that add value to the final product because the customer is willing to pay only for this added value. [1]

By combining interactive games and lean manufacturing principles we get a powerful tool both for effective utilization of human resources in terms of time demands of the adoption of these principles by employees. Employees then further extend these principles to the production process.

Basic description of managerial game

It is a desktop management simulation game that demonstrates how to improve the organization of production and workplace downsizing. Production is stimulated in a way that players take the role of workers in the workplace, and gradually assemble the product. The game is suitable for 4-5 players, and playing time is variable from one hour to three hours. The presence of a moderator during the game is very important. The moderator must be thoroughly familiar with the principles and rules of the game, but also the theory of the methods that this game demonstrates.

The game consists of two main parts. The first part is used to display the original state. At this stage the production organization is given either: intentionally wrong or not clear, or it is unknown for a, in order to demonstrate that it is insufficiently systematic.

The main content of the second part is a gradual improvement. Players are introduced to several methods which can improve production. The task of the players is to point out the deficiencies that were reflected in its original state and then invent the order in which lean manufacturing methods will be implemented so that they follow and gradually improve the entire production.

The first part of the managerial game - Simulation of the original state

Players are at various positions around the room. To maintain the universality of the game it is not possible to prescribe a specific room of the specific size and with the same equipment, so this step is rather at the moderator. Generally, you can specify that players must spread out across the room and not to concentrate on one or two tables. At the same time two other locations are indicated somewhere in the area. It is a material warehouse and warehouse with finished products.

The facilitator explains the rules for the round to players, rounds length is 5 minutes. An assessment is based on the fact that the number of finished products is compared with the planned amount in each round.

Depending on the number of players available, the game will either go towards maximum utilization of existing workplaces (4 players) or via the maximum productivity of the entire production line (5 players) and the moderator has to adapt the game, it in particular concerns phase "balancing line".

Rules:

- Each player represents one worker and all players are located variously around the room.
- Each playing piece is identified as a "Store of material" and a place for warehouse of finished products is also marked.
- Each player gets a production plan of the product.
- Players take positions at their workplaces, they go to the material warehouse, where they have to find enough pieces to build the product.
- The product can be manufactured only at their workplaces, and once the product is manufactured, players put it into the warehouse of finished products.
- Other arrangements are up to the players.

Players must first orientate themselves in the new environment, they have to study the production plan of the product and think about preparation. Players must go to the material warehouse, where they have to look for the pieces together with other players and after manufacturing of the product, the product will be placed in the warehouse of finished products. In this phase a confusion, errors in the products, pieces substitution, delays in material storage, etc. are expected and all of these result in a wasting in the form of unnecessary transport, scrap, waiting, unnecessary movements, etc., which leads to the low number of assembled products. After the end of playing time the moderator stops player and finds the number of final products. Then further evaluation will take place.

Evaluation of the first part of the managerial game

After the first part there is a discussion between a moderator and players. Players are asked to evaluate an original condition and pointed out all the flaws that have emerged during the game. Most of the deficiencies is for a game clarity really obvious, but if players forget to mention any of them, moderator does it. Once players know all these problems in production, it will be easier for them to think about their elimination in other part of the game.

The second part of the managerial game - Better organization of production

The following methods and lean manufacturing principles are presented to players:

- Professional staff training (basic training)
- Standardization of del REFA standard
- Operations balancing
- Layout edit
- 5S

The player has to think in group and sort methods in the order in which they will be introduced to the workplace, in order to improve production and leaner workplace. For their function certain methods and tools require introducing some of the other methods, or vice versa after the introduction of additional methods they lost their effectiveness. This is clearly shown in the matrix below. The moderator should lead players to the expected results through appropriate questions and comments, but above all players should think about it themselves.

	Method of implementation (following)					
Implemented method (previous)		**Training**	**Layout**	**Standardization**	**Balancing**	**5S**
	Training		**Yes, when workers already know the basic job description, it is possible to make further changes**	First it is necessary to realize basic training	First it is necessary to realize basic training	First it is necessary to realize basic training
	Layout	First it is necessary to realize basic training		**Yes, after changing the layout standardization of operations can be done**	It is not possible to balance operations, unless there are standards, specifically the times of operations at workplaces	It is not possible to adjust, tidy, clean, all clearly organize etc., and then change the entire layout
	Standardization	First it is necessary to realize basic training	The change of standardized workplace layout would result in a change of distances as well as a change of times and standardization would be unnecessary		**Yes, after standardization and finding times of operations, it is possible to balance operations**	There are times of operations, but without subsequent balancing is 5S useless
	Balanci	First it is				**Yes, 5S is finally**

	ng	necessary to realize basic training	The change of standardized workplace layout would result in a change of distances as well as a change of times and standardization would be unnecessary	Standardization at balanced workplace has no longer any meaning		**introduced at balancing workplace for better understanding and overview of production**
	5S	First it is necessary to realize basic training	Changing the layout of workplace, where 5S is implemented, would reverse the entire original 5S	Standardization and balancing of all workplaces cannot be done after 5S	Balancing the operations of all workplaces cannot be done after 5S	

Figure 1: Matrices of methods and principles of lean manufacturing implementation

Professional training

In the first phase of the game workers were placed into full operation without sufficient training. Orientation in the workplace, studying of manufacturing drawings, figuring out how to assemble products etc. took them more time than actual production.

Therefore it was mostly wasting of resources than a productive activity. This involves:

- Presentation of all parts required for the product manufacturing.
- The opportunity to try several times to assemble test product.
- Notify pieces of kit that can lead to confusion.
- Explain the most efficient method for assembling pieces

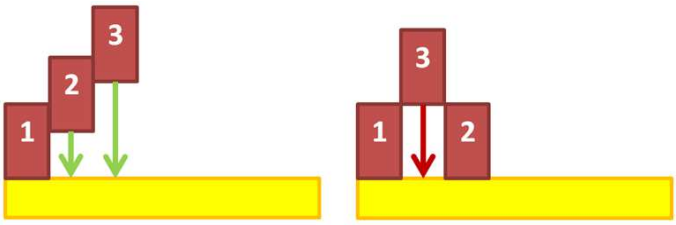

Figure 2: Appropriate and inappropriate system of assembling pieces

Standardization according REFA standard

On the production line there is one workplace, which is a bottleneck. Namely it is workplace number 2 and all players should already know this fact. This bottleneck must be removed as soon as possible regarding the fact that because of it the whole production is slowed down. This leads to a waste of resources, especially in the form of waiting and excessive amounts of work in process before the bottleneck and the production line is therefore inflexible.

Two workers will assemble the product from pieces exactly as they would be for a real round of the game. The other two players will measure time of joining two pieces together for these workers. More specifically, it is the time interval from griping to "snapping" the piece into the counterpart. It is

not necessary to assemble the entire product because all operations are regarded as about the same length.

After obtaining a sufficient quantity of values all of these values are written into the appropriate table in a prepared Excel file and the average length of a single operation, which should be about 2.5 seconds, is determined. Also, players should decide whether there are more time-consuming operation or whether it is possible to consider all operations as the same long.

Balancing of operations

Players use obtained and measured values to eliminate the bottleneck in the workplace. If there are only 4 players, existing workplace will be maximally utilized. If there are five players, it is possible to play the game for a maximum efficiency of the whole production line and workplace, where is a bottleneck, will be reduplicated in this way.

Layout editing

Editing the layout may consist of the following steps:

- Workplace organized into lines. Workplaces are placed in the way that each other immediately followed.
- The entire production line is placed on one or two benches (according to the propositions of the room)
- The distance between workplaces must be minimized.

5S

Now, when the production is stabilized and smoother it is possible to start with introduction of 5S method.

- 1S: Sort all unneeded.
- 2S : Set in order all the rest
- 3S : Shine - to pay attention to cleanliness and order
- 4S : Standardize
- 5S: Sustain is 5S and keep improving.

The first two "S" are already introduced in the workplaces system in the form the layout changes and workplaces placement in a row. This phase of the game focuses more on the 3rd and 4th S and manifests itself as follows:

Players take out the material (parts of the kit) from the boxes

- From the moderator all players will receive documents as the "Material warehouse," "Unfinished products warehouse" and "Finished products warehouse"
- Players will place pieces of the kit at the appropriate fields, which can be found on the basis of images on the "Material warehouse" card
- Unfinished production between workplaces will be always placed to a field in the "Unfinished production 1" card or card 2 and 3 for other workplaces.
- Final products will be placed in the field on the "Finished products warehouse" card.

Conclusion

The new interactive game for the application of lean manufacturing principles in automotive showed significant benefits that represent mainly the effective training of new employees, promoting creative thinking, eliminating the possibility of error during the real production process - quality assurance process.

Presented savings are determined by the quality of the moderator of games, who is an integral part of this interactive game. The moderator has think ahead about the direction of the game and following steps. This interactive game was tested during five trainings in automotive companies, where above-described benefits were confirmed.

Abstract

This article aims to highlight the importance of warehouse inventories and the need for their effective management. This article contains information regarding the relevance of inventory and internal logistics in company in general. The article also contains basic principles, meaning and importance of analysis of inventory - namely ABC analysis, XYZ analysis and a combination of both analyses, it means the resulting matrix ABCXYZ, through which we can recommend appropriate way of managing the flow of inventory. Case study that shows the use of analyses and their possible benefits in practice, is also included in the article.

Keywords: Inventory Management, Internal Logistics, ABC Analysis, XYZ Analysis, ABCXYZ Analysis

Introduction

Among the essential items in terms of share in the assets of the company certainly includes an inventory item, which usually forms the most important part. Inventories bind significant capital of the company for some time. Likewise logistical processes associated with the acquisition, storage and distribution of inventories also require significant costs. From the above it can be concluded that every company should strive to minimize inventories and to "hold" the minimum amount.

Another important factor that makes the whole issue even more complicated is a nowadays highly competitive environment. If a company wants to be competitive in the market, it must be able not only to maximally meet diverse wishes of its customers, but also to react quickly to these wishes. This fact in the contrary leads to a tendency to keep large quantity of inventory which is however a significant economic burden for the company.

Above-mentioned facts are the reason why it is necessary to pay proper attention to the issue of inventory management and associated processes. But interests of different departments across the company are as contradictory as the above mentioned facts. While business and production departments prefer to keep a sufficient amount of inventory, including emergency inventory, economic department would prefer to purchase them just before consumption. A logistic department are facing a difficult task, namely somehow manage the discrepancy between the needs of sales and financial pressure.

Analysis of inventories

That workers of the logistics department can efficiently manage inventories, they need to know not only patterns of production and inventory management company, but also need to get a comprehensive view of inventory, which is achieved only by detailed analysis. The diagram below outlines possible procedure of inventories analysing and the partial results of analysis.

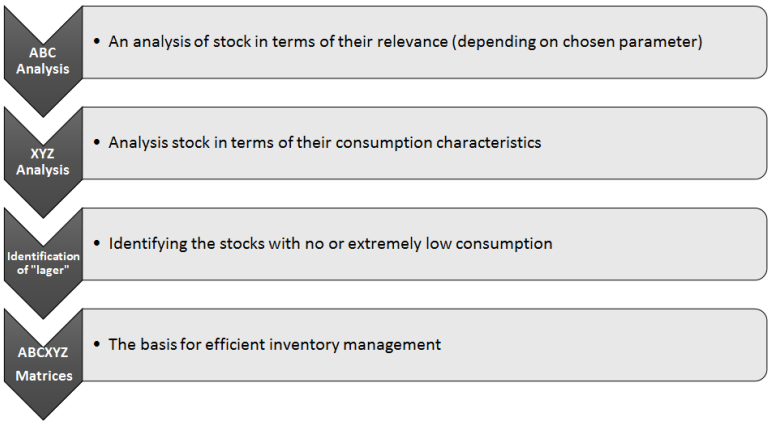

Figure 1: A flowchart of analysis of inventory

Mentioned analyses have been widely described in various articles such as Pekarčíková, Trebuňa, Filo (2014) or Scholz-Reiter, Heger, Meinecke, Bergmann (2012). Because of it this article describes only the basic principles of analysis without detailed description. Subsequently, a case study from which the use and outputs of these analyses in practice is obvious, is described.

ABC analysis

ABC analysis is a widely used method in the corporate logistics. The analysis is based on the so-called Pareto rule, which says that 80 % of all consequences are caused only about 20 % of causes. ABC analysis is thus based on division of items into three categories in terms of their importance, the parameter determining their importance may vary depending on the observed problem. By the categorization it is possible to achieve considerable savings, as the attention of the company and the associated time, space and money are devoted to significant items, it means items for which it makes sense.

XYZ analysis

XYZ analysis is an analysis used for an evaluation of inventories in terms of their timing of the consumption or sale, reliability and predictability of their consumption. The analysis is used as a basis for decisions which logistics technology would be the ideal one for inventories management. XYZ analysis itself does not provide complete results, therefore it is advisable to combine it with the above described ABC analysis.

ABCXYZ matrices

So called ABCXYZ matrices, which adds further insight into the way of work with different inventories and which serves as a basis for possibility of effective inventory management, is formed by combining above mentioned analysis. Matrices divides inventories into nine categories, depending on their significance and regularity respectively predictability of consumption. Features of each group can be seen in the table below. Attention should be paid to items of AX, AY and AZ as they form a major part of the turnover and therefore are assumed for the high inventory levels. Items BX and CX

have a very regular consumption and can therefore be relatively easily predicted. Due to lower significance of these items they are not assumed as core items of the company.

Table 1: ABCXYZ matrices[1]

	A	B	C
X	a large share of turnover regular consumption	medium proportion of turnover regular consumption	small share of turnover regular consumption
Y	a large share of turnover consumption with fluctuations	medium proportion of turnover consumption with fluctuations	small share of turnover consumption with fluctuations
Z	a large share of turnover irregular consumption	medium proportion of turnover irregular consumption	small share of turnover irregular consumption

Appropriate logistics technologies are then recommended for each category. There are several approaches, one of them is shown on the scheme below. It should be realized that these recommendations cannot be taken as dogma. It is always necessary to take the specific nature of materials, nature of particular production and other conditions into account.

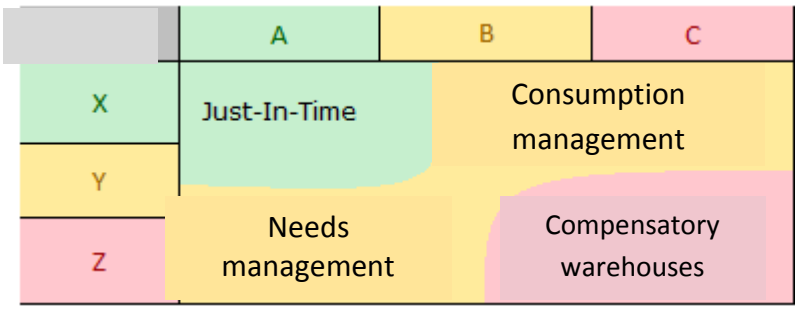

Figure 2: ABCXYZ matrices – logistics approaches[2]

Case study

An unnamed industrial automotive company manufacturing cable harnesses produces in total of 6 production halls. Each of the production halls has a production warehouse into which the material is regularly transported from central warehouse about 50km away. The company currently divides material on so called A-parts, B-parts, semi-finished and finished products. A fundamental difference

[1] *Reference: http://pu-del.ch/webseite_case_study/_private/hauptstudie/bereitstellungs.htm*

[2] *Reference: http://www.der-wirtschaftsingenieur.de/index.php/abc-xyz-analyse/*

between A and B parts is in the way of picking up to production. Currently, A-parts are picked[3] from production warehouse directly to production on demand, it is about 80 % of the material. B-parts are placed directly in production, in so-called supermarkets, where each production line has the particular shelf where workers can take and return back the material as needed.

The basic parameters which are the base for sorting materials into specific groups include the character of the material and the frequency of use of a particular material on a particular production line. But in fact, no fixed system on assessing the material does not exist. However, the common practice is that upon entry into the company material is added to the appropriate category on the basis of experience of the workers and in case of unsatisfactory state there are disputes between logistics and production about changing the material classification.

Another problem associated with almost nonexistent system of materials assessment was that production had to often deal with so-called backordered A-parts. This was mainly due to inaccuracies in the warehouse when the material was incorrectly counted or weighed or because of inaccuracies in production, where it can be considered as a common scrap.

The situation in the company caused a necessity to carry out the analysis of input material, which would help to establish the system of material categorization and assign the appropriate logistics technology. More than 45,000 items in total were analyzed.

As first, so-called ABC analysis when individual components are evaluated for their contribution to the mean inventories value was performed. Analysis results are shown in the following table.

Table 2: ABC Analysis

group	number of items	the ratio in the total number	medium inventories value (CZK)	the ratio of the overall medium inventories value
A	3 000	6,60%	497 692 459,95	81,00%
B	4 744	10,44%	79 885 132,94	13,00%
C	37 703	82,96%	36 869 946,50	6,00%
Items in total			45 447	
The overall medium inventories value (CZK)			614 447 539,39	

Subsequently, an analysis of so called "lying item" was done. A "lying item" is considered such an item in which there has been no movement[4] from 1st January 2015, all other items are considered to be so called "active items". The analysis showed that more than about 35 % material items belong to the "lying items" that bind significant capital of the company, and more specifically, over 166 million Czech crowns.

[3] *This means that they are prepared by internal pickers directly to order – all the necessary quantity is weighed or counted on order, divided into bags and assembled into the appropriate KLT or other transport units.*

[4] *Note: analysis was conducted in September 2015.*

Table 3: Lying items analysis

	Lying items	Active items	Total
Number of items	16 108	29 339	45 447
Ratio (in %)	35 %	65 %	
Inventories value (in CZK)	166 918 861	447 528 678	614 447 539
Ratio (in %)	27%	73 %	

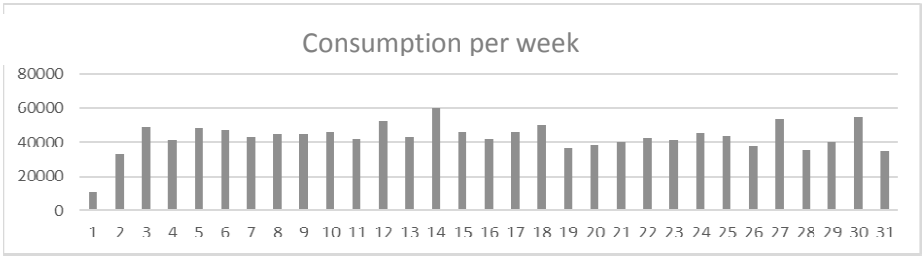
Subsequently, an XYZ analysis, which was carried out for each production halls separately, was done. In this article, we'll cover only selected production halls - Hall 3 and 4. Data provided by the company included daily consumption in the period from 1 January to 31 July 2015, it means in the period of 7 months. During the analysis daily consumption was converted to a weekly one. Results of the analysis are shown in the table below.

Table 4: XYZ Analysis

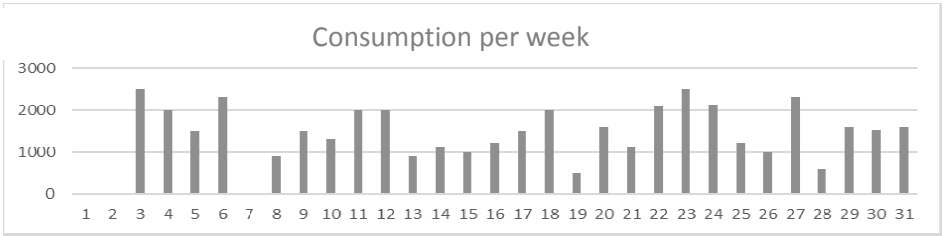
XYZ Analysis - WH 3		
Group	Items frequency	
X	160	13%
Y	314	25%
Z	797	63%
Total	1 271	100%

XYZ Analysis - WH 4		
Group	Items frequency	
X	74	6%
Y	180	14%
Z	1008	80%
Total	1262	100%

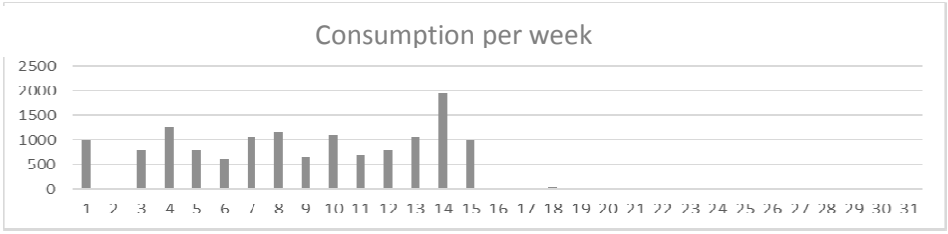
In figures below a regularity of consumption for each of the above mentioned analysis is illustrative. The graphs show how regular is a consumption of the material in the X category, which has the most regular consumption. Some kind of fluctuations can be seen regarding materials at the turn of categories X and Y. Material consumption at the turn of categories of Y and Z is already very unlikely and therefore very difficult to predict. Regarding material from Z category where consumption is entirely coincidental, any notion of predictability of consumption is practically unrealistic. Graphs below show how regular is consumption per week of chosen part numbers (PN).



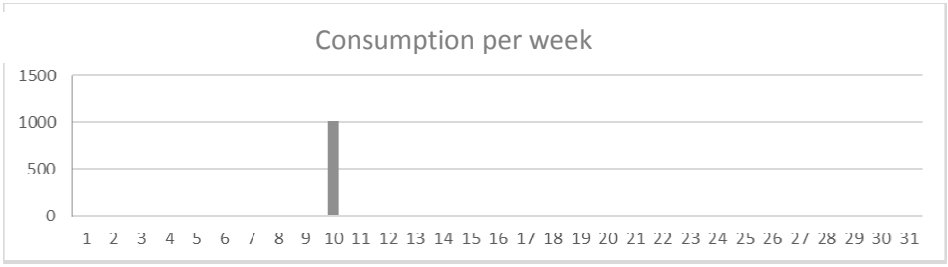
Graph 1 – Consumption/week – chosen PN – X with irregular consumption.



Graph 2 – Consumption/week – chosen PN – turn of X and Y.



Graph 3 – Consumption/week – chosen PN – turn of Y and Z.



Graph 4 – Consumption/week – chosen PN – Z with the least regular consumption.

Finally, the analysis of ABC and XYZ incorporated together and become the matrix ABCXYZ (again for each production facility separately), based on which we can recommend appropriate logistics technology.

Table 5: ABCXYZ Analysis

ABCXYZ ANALYSIS - WH 3

GROUP	Items frequency		Recommend.
AX	133	10%	Supermarket
AY	120	9%	Supermarket
AZ	124	10%	Supermarket
BX	18	1%	Kanban
BY	71	6%	Picking
BZ	132	10%	Picking
CX	9	1%	Kanban
CY	123	10%	Picking
CZ	541	43%	Picking
TOTAL	1271	100%	-

ABCXYZ ANALYSIS - WH 4

GROUP	Items frequency		Recommend.
AX	68	5%	Supermarket
AY	72	6%	Supermarket
AZ	147	12%	Supermarket
BX	4	0%	Kanban
BY	61	5%	Picking
BZ	112	9%	Picking
CX	2	0%	Kanban
CY	47	4%	Picking
CZ	749	59%	Picking
TOTAL	1262	100%	-

Analysis outcomes including recommended logistics technology are evident from the table. It should be noted that the analysis did not take into account the nature of the material. It means that certain parts will not be practically possible to supply to the production in the way of proposed method (e.g. regarding their nature contacts cannot picked into the production).

And what were the particular benefits of analyses, which were carried out? A clear system of categorization of materials between the A and B parts was established. Items belonging to the group of "lying items", which require a certain response from the company, were also discovered. Subsequently, the material was classified into categories in terms of its significance and in terms of regularity and its consumption respectively predictability. By combining both analyzes a basis for effective inventory management was obtained. Additionally, analysis revealed that the top 10 most additionally ordered items in terms of the frequency of additional orders and in terms of overall additional orders amount include items that are currently picking, but according to results of analyzes

these items should be directly in manufacturing supermarkets, which would also largely solve a problem related to additional orders.

Conclusion

As has already been outlined in the introduction, the issue of inventory management is a very complex task in practically every company. It is also necessary to pay attention to inventory control due to importance of inventories in the company. Is practically impossible to effectively manage inventory without the knowledge of inventories nature, consumption, significance, availability, etc. Thorough and regular analysis of inventories enables efficient inventory management. The company may invest their time, money and space primarily to significant items, because in relation to them it makes sense. Effective inventory management can not only save the cost of the actual management (as an attention is paid to the significant items) and storage (because the company maintains inventories only in an amount corresponding to the nature of the item) but it can also prevent problems arising in production in relation to lack of inventories or unsuitable form of supply and extra costs associated with that.

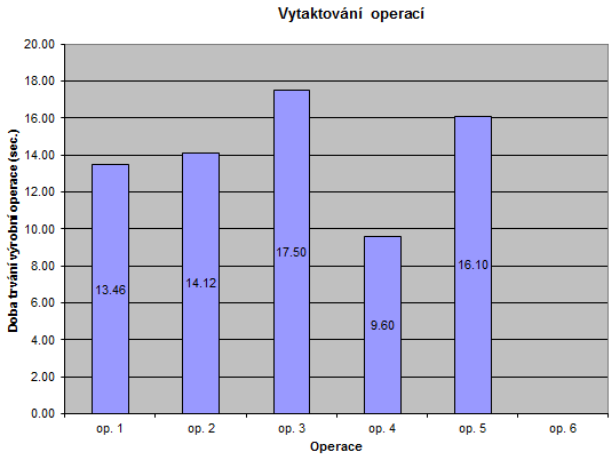
Abstract

A key part of every logistics chain are warehouses. Each warehouse can be divided in terms of the movement of the material into input (income) section, a storage section (physical store) and the output section (expedition). Physical movement of material is always accompanied by administrative operations.
According to the theory of bottlenecks entire system is as efficient as effective is its weakest point. This article deals with both material and immaterial flow in the entrance of the storage system, identifies bottlenecks of sub-processes, for which it proposes and evaluates corrective actions.

Introduction

Bottleneck or constraint was defined by Eliyahu M. Goldratt (Goldratt, E. (1999)), who created a method for increasing the flow through the system. Illustratively we can define constraint as a place with the smallest flow. It is exactly the place, whose maximal flow rate determines the maximum output flow through pipe. In the production management this analogy can be found, for example, in production lines, which build on each other several stations linked, for example, by a conveyor belt. For each machine station the time that is required to meet specific operations can be assigned (either by calculation - MTM methods or elevation - REFA analysis). After that the operation with the longest duration of time determines flow through (production capacity) lines. Operation with the longest time duration are called by (Goldratt, E. (1999)) bottlenecks. Figure 1 shows a production line balancing. Height of the bar indicates the time of the operation. For the calculation of the production line capacity is required to use the longest operation.

During the rationalization of the storage process we are getting to the same situation, only the columns of manufacturing operations are replaced by the columns of the processes associated with receiving the material, its physical unloading, marking, unwrapping, handling, storage, etc.



Storage

Basic functions of storage systems are to move products, to storage them and transmission of information about storage products. These functions inevitably include the following processes:

- Receiving incoming goods and materials (including physical unloading, inspection according delivery notes and quality requirements)
- Storage of material and goods
- Release of goods for processing
- Storage and dispatch of finished products or semi-finished products

Each of these processes involves some specifics. Processes associated with the storage are described in detail in publications (Lambert, S. E., 2000), (Pernica, P., 2005). The paper deals only with part of these processes, namely receiving of incoming material and goods to the warehouse. The latter process, namely storing materials and goods to the warehouse, is affected by its nature.

Receiving into warehouse

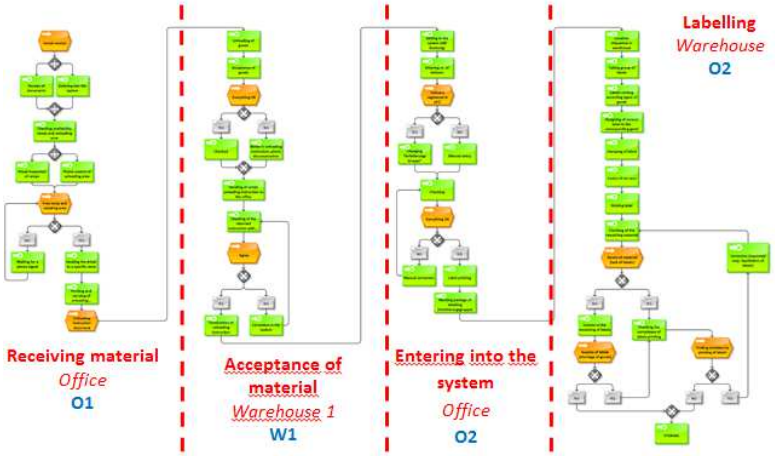
Receipt of materials and goods to the warehouse includes an income based on the invoice, delivery note or receipt. Receipts can be modified, for example, it is possible to add additional items of schedule until the completion of daily processing income. Receipt of material is usually accompanied by physical inspection of the completeness of the delivery and quality control of delivered material or products. After a successful takeover, it is necessary to mark the material and move it to the place of its storage. Due to the focus the article, in which we do not discuss the optimal way of handling the material or its method of storage, we will focus only on the first of these sub-processes, specifically its income and marking.

Case study

The case study was prepared in the automotive enterprise, engaged in the manufacture of parts and accessories for motor vehicles, further processing and making-up of cables. The project of proposal for a new process of receiving material consists of an analysis of activities related to material income and material rationalization including the introduction of new technologies in order to:

- Minimization of error process (quality assurance)
- Minimization of complaints and the associated additional costs
- Streamlining the entire receipt of material process
- Shortening the duration of the process
- Increase the smooth flow of material

The entire receiving process was mapped, described, analyzed and organized into four key parts Material receipt, Acceptance of material, Entering into the system, and Labelling, see Figure 2.



During the analysis bottlenecks were identified across all key parts of the receiving material process. Each part has its bottlenecks (incomplete documents, ramps occupancy, manual operations, long distance, etc.), the most crucial problem, however, is input into the system and sticking labels on individual HU.

Data entering into the system

On the basis of measurements 72,385 HU from 969 suppliers in total were recorded during the month.

The analysis showed that only less than 45% from total number of suppliers entered the supply into the system, which is 65%. The remaining 55% of suppliers do not send anything to the system and a supply must be entered manually, which takes time, determining the proportion of one handling unit, on average for 1.80 sec./HU longer, which corresponds to nearly 25% of the total labor pool (434 hours with the current number of labels) per 1 employee per year. If the remaining 55% of suppliers have entered supply into the system, the company would save an average of 12.82 hours / month.

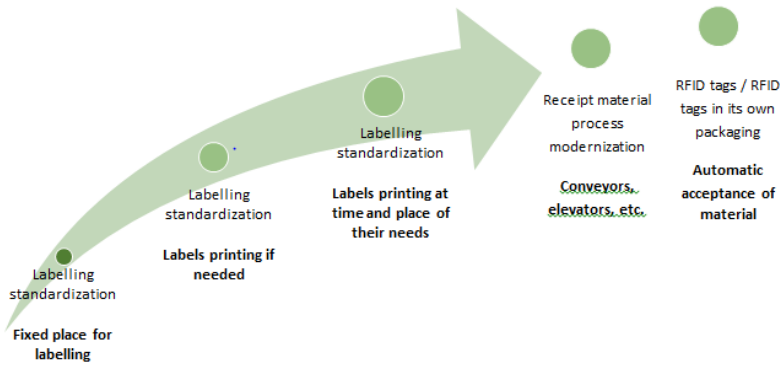
Labeling process

The table below certify that labeling itself is the least effective and the most time-consuming and financially demanding sub-processes of the whole process of goods receipt to the warehouse. The time of the entire process is on average a total of 39.14 sec. /1HU, of which more than 85 % of the time is spent by labelling itself, which takes an average of 33.38 sec. /1HU.

ID and the name of subprocess	O1 Material receipt	O2 Acceptance of material	W1 Entering into the system	W2 Labelling	Total
Workplace	**Office**		**Warehouse**		**-**
Time (sec./HU)	**5,76**		*Not measured*	**33,38**	**39,14**
Time (hour/day)	6,03		-	34,93	40,96
Time (hour/month)	126,59		-	733,58	860,17
No. of employees shift/day	0,75		-	2,25	3,01
Costs (EUR/day)	49,10		-	204,51	253,61
Costs (EUR/month)	**1 031,10**		**-**	**4 294,79**	**5 325,89**

Proposal for a new intake of material in stock

Performed analysis has confirmed that it is necessary to streamline the entire labeling process, and to propose a new process in terms of time and financial cost optimum. Process visions, which were implemented in the third phase (see Figure 3 below) were designed.



The table below compares the different phases in numbers. Table 1 shows the estimated time for labeling process, operating costs, investment demands of alternatives, potential savings and return of each alternative is calculated as well.

Alternative	**Current state**	**A** **Mobile printer**	**A** **Labelling trolley**	**B**	**C**
Total time - labelling (in sec.)	**33,38**	**25,34**	**25,34**	**28,66**	**26,46**
Total operating costs (in EUR/HU)	0,06	0,07	0,05	0,05	0,05
Investments costs - HW equipment (in EUR)	-	**€ 5 708,73**	**€ 13 416,00**	**€ 9 325,09**	**€ 9 325,09**
Potential saving (in EUR/month)		-€ 616,90	€ 1 048,69	€ 615,65	€ 902,60
Return (in months)		**-9,25**	**12,79**	**15,15**	**10,33**

Potential savings that are expected do not include perhaps the most important item - namely saving the extra costs associated with internal label exchanging respectively mislabeling. Mislabeling or low quality during the process of labeling is called soft savings and because of this it cannot be precisely quantified.

After considering the advantages and disadvantages of different alternatives described in the previous chapter and the results summarized in the table above alternative C, which estimated payback period is from all the considered alternatives the lowest one, seem to be an optimal one. Additionally, it is possible to consider the option C as an ideal preparation for the subsequent introduction of alternative D.

Conclusion

The new process of goods receipt to the warehouse will streamline the entire labeling subprocess. Significant benefits primarily relate to the elimination of the possibility of error during the process - quality assurance process by minimizing complaints, ensuring a smooth flow of material in stock due to savings in storage space and the space needed for the reception and the possibility of introducing shorter than the weekly planning, shortening the duration of the entire process of receiving material due to savings in staff costs.

Presented savings are dependent on the assumptions of the new goods receipt to the warehouse process proposal. And the proposal for a new process of receiving material in stock presume the introduction of these improvement measures: appeal to the contractor in connection with the incompleteness of documents from drivers, purchase of additional copiers for receipt of material office and its appropriate positioning, the introduction of electronic visualization and sending the print of the "Instruction for unloading" straight to responsible person in the warehouse.

The Role of European Funds in Romania for the Development of Tourist Accommodation Infrastructure

Alexandru Virgil Taşcu, Bucharest University of Economic Studies, Bucharest, Romania, tascu_alexandru_virgil@yahoo.com

Abstract

Romania, among the countries of Central and Eastern Europe, is vested with the most rich and diverse natural and anthropogenic tourist resources, which gives it a high-availability tourism. Rural tourism and farm tourism developed significantly in Romania, and one can say that it aligns increasingly more to the European standards in this area. European funds are financial instruments through which the Union is working to reduce economic and social disparities between regions in order to achieve social and economic cohesion between regions and Member States. In Romania, the construction of a tourist boarding house by accessing non-reimbursable European funds is possible through the National Rural Development Program (NRDP) and the Regional Operational Program (ROP).

Keywords: European Funds, tourism, accommodation, infrastructure.

Introduction

It is a known fact that tourism represents a factor of economic progress at a global scale and a decisive element for the development of the entire society. In this context, by means of introducing the cultural and historic heritage, the natural resources and certain modern achievements in the field of architecture and art in the internal and international economic landscape, tourism brings dynamics into the economic and social system contributing, at the same time, to the optimisation of the local economy structure, and thus being the optimal solution for the diversification of economic structures. Therefore, the topicality of this subject derives from the fact that maximising the use of tourism potential requires an improvement of the mechanisms designed to manage this sector of modern economy.

In order to provide quality touristic services, it is mandatory to have a modernised accommodation base, an infrastructure meant to receive tourists at the highest level, the tourist offer comprising the attractiveness of sights and objectives representing only one of the prerequisites.

"The interdependence between (international and domestic) tourism development and economic growth is obvious since it drives the demand for a series of goods and services which would not have otherwise been manufactured or rendered" (Snak, 2003). Alluring tourists is an activity which has to be taught and learned by the business operators involved in Romania's touristic activity, in circumstances in which this field ought to be supported and developed according to the market economy laws.

In view of stimulating tourism, the executive guidance of the cohesion policy for the 2007-2013 programming period comprises concrete measures designed to contribute significantly to regional development and the creation of jobs. In that respect, the improvement of competitiveness and tourism quality both at a regional, as well as a local level, can be financially supported by accessing non-reimbursable European funds. Given these circumstances, even in industrial or rural areas in decline or those undergoing urban rehabilitation works, the infrastructure built for touristic activities can contribute to local development, by providing new jobs or keeping the current ones. Thus, tourism represents a factor for the integration of less developed regions and a tool which provides them with equal access to the benefits of economic growth.

The framework for accessing European funds in Romania

The goal of financing through European funds is to promote a high competitiveness level so that the member states may take advantage of a series of several benefits: the free circulation of people, a free market with a currency facilitating and optimising commerce, the creation of jobs, an improvement in the employees' rights, and the promotion of a cleaner environment. The Structural Instruments represent mainly a policy of European cohesion and are funds managed by the European Commission for the 2007-2013 programming period, whose purpose is to provide structural support as far as 3 policies are concerned:

The European Union's Economic and Social Cohesion. "For the 2007-2013 period, the European Union's cohesion policy was reformed in order to better address the goals set forth in Lisbon and Gothenburg (competitive economy relying on knowledge, technological research and development, sustainable development, employment)"

(http://ec.europa.eu/romania/eu_romania/romania_eu/funds_romania/index_ro.htm). The cohesion policy is financed through the European Regional Development Fund (ERDF), the European Social Fund (ESF) and, the Cohesion Fund (CF), respectively, and aims at diminishing disparities and lowering the difference in the development levels of various regions and member states, in order to consolidate economic and social cohesion. The financial solidarity principle, which is the redeployment of a part of the community budget towards the less prosperous regions and social groups, accounts for the grounds of this community policy. The cohesion policy has 3 critical objectives, as follows:

- ***Convergence*** or the reduction of development gaps between regions. The states may request funding for the regions scoring a gross Domestic Product per capita below 75% of the European average.

- ***Regional competitiveness and employment***, which applies only to regions that are non-eligible for funding within the Convergence objective. With regard to Romania, all 8 regions are eligible within the Convergence objective.

- ***European territorial cooperation***, in support of modernising and adapting the work force education, training and employment policies and systems.

Common Agricultural Policy.

The Common Agricultural Policy (CAP) is financially supported by the European Agricultural Fund for Rural Development (EAFRD) and aims at ensuring the food requirements within the Community (the European Economic Community) and rural development, being one of the first community policies. This European policy represents a set of rules and mechanisms which regulate the manufacture, processing and marketing of agricultural products within the European Union and pays an ever growing attention to rural development.

Common Fisheries Policy.

The Common Fisheries Policy (CFP) is financed by the European Fisheries Fund (EFF) and comprises the measures set forth by the European Union in view of guaranteeing the sustainability of fishing activities, without endangering the fish stocks and the sector productivity in the long run. Additionally, it represents a set of rules applicable to the European fishing fleets and designed to preserve the fish stocks which, even though they can be renewed, remain limited. The common fisheries policy provides all the European fleets equal access to the EU waters and the fishing areas and allows fishermen to compete in a fair manner.

In order to access the European funds provided to Romania, following its accession to the community space, a specific institutional and legislative framework was created for managing, coordinating and

implementing the Structural Instruments and, at the same time, the national and the community legislations became harmonised, the institutional structures thus created being similar to the European structures.

Development of the Romanian touristic infrastructure

Starting from the premise that tourism represents a critical element in the economic development process and considering the fact that Romania enjoys a rich a diversified natural environment, numerous natural and anthropic touristic resources, one can state that this sector holds a major role in the country's economic and social, being nevertheless necessary to focus on elevating the quality of the services provided.

„In general, the tourism form may be defined by means of the actual expression adopted by the association/combination of services (transportation, accommodation, food, entertainment, treatment) comprised in the tourist product, as well as the manner of marketing it" (Neacșu, 2012). By launching the concept of Romanian "touristic village" on the domestic, and especially on the international market, the Romanian rural tourism is one of those offers able to create quality and various touristic products, with local specificity, thus contributing to the customisation of the Romanian touristic product. The complex connections emerging between tourism and other economy sectors may determine modifications at a territory level, contributing this way to the economic and social development of the trailing or resource-deprived regions.

Habitats intended for exploration and relaxation can be found all over the country, each enjoying its own customs and regional specificity, whereas services are directly correlated with the chosen area. There are also regions, such as the Rucăr-Bran passage, where rural tourism improved the inhabitants' standard of living, as these understood the agricultural tourism concept and provide, in addition to accommodation and meals, a multitude of pastime activities - hikes, traditional evenings, horse riding, fishing matches, adventure parks, camp fire parties, as well as special offers for the holidays period. The difficult access to certain areas, only by car (Apuseni Mountains, Buzăului Mountains, Banatului Mountains, the Outskirts of Sibiu, the Eastern side of Transylvania Depression) or limited to a single means of transportation (the Danube Delta), renders regions with an invaluable cultural heritage and an immense natural potential touristically unexploited.

From an economic standpoint, tourism turns out to be a progress factor, with vast and positive implications upon the development of the entire society. Thus, by means of acting in the sense of introducing in the (domestic and international) economic circuit the natural resources, the cultural and historical heritage, which have a lot of appeal, and some of the contemporary achievements in the fields of constructions and art, tourism becomes a stimulating factor of the economic and social system, a means to diversify economic structures and an optimising factor of the local economic structure.

Financing a tourist reception unit with European funds

In order to be classified as tourist boarding houses, tourist reception structures with lodging functions, as per the provisions of GD no. 709/2009 on the classification of tourist reception structures, must have an accommodation capacity of up to 10 rooms, for a total of 30 beds, in the rural area, and up to 20 rooms in urban areas. At the same time, these must also operate in private dwellings or independent buildings, and provide tourists with lodging and meal services.

Modern tourism relies on the observance of elevated standards with regard to the building and quality characteristics. Thus, the procurement of non-reimbursable European funds also involves the observance of comfort and quality norms, driving the development of domestic tourism and agricultural tourism, sectors affected by deprivation and until recently limited to insufficient lodging facilities and standards below what the European market has to offer.

"Potential challenges regarding the structural and cohesion funds relate to the ability of institutional and administrative structures to manage these funds" (Florescu, 2012). In Romania, the construction of a tourist boarding house by accessing non-reimbursable European funds is possible through the National Rural Development Program (NRDP) and the Regional Operational Program (ROP). For NRDP, the institution in charge with the technical and financial implementation of the European Agricultural Fund for Rural Development (EAFRD) is the Payments Agency for Rural Development and Fisheries (PARDF). For the Regional Operational Program, within the Ministry of Regional Development and Public Administration, the Management Authority was constituted for the purpose of implementing in Romania the European Regional Development Fund (ERDF) and facilitating "the support for a territorially balanced and sustainable economic and social development of Romania's Regions, according to their specific needs and resources, by focusing on the growth urban poles, and improving the infrastructure and the business environment conditions so as to turn Romania's regions, particularly the trailing ones, into locations more appealing to live in, to visit, to invest and work in" (http://www.fonduri-structurale.ro/Detaliu.aspx?t=Regional).

The National Rural Development Program

In order to access funds made available by NRDP, through measure 313, micro businesses have to fulfil a series of conditions in view of building structures for tourist reception in the rural area. Thus, one may finance, as part of this program, various types of accommodation units with a maximum number of 15 rooms. For agricultural tourism boarding houses the quality standard must be at least one daisy, whereas for investments carried out in tourist reception destinations from other categories at least 3 stars/daisies are mandatory. One may finance such infrastructures in other touristically significant areas, as well, not just in rural areas, but eligibility is granted only to modernisation and extension activities, which require the increase of comfort standards by at least one star/daisy.

In compliance with the provisions and conditions imposed in the applicant's guides, the funding of extensions and even for reshaped fields of interest are only possible if detailed studies intended to thoroughly justify such actions are carried out. For agricultural boarding houses the EU co-financing is 70%, within the 70,000 Euro limit, and for tourist boarding houses it amounts to 50%, within the 200,000 Euro limit. In the assessment of the proposed investments, the criterion with the highest share is project feasibility, given that 50% and 70%, respectively, grants the EU non-reimbursable funding. In the assessment process, the scoring shall depend upon location, maximum points being awarded if the land opted for benefits from all the utilities, is not very remote and offers picturesque sights.

The general goal of measure 313 is to develop tourism-centred activities in rural areas, which would help increase the number of jobs and alternative incomes, as well as elevate the appeal of the rural space. The general goal of measure 313 regards the development of touristic activities in rural areas, but it also covers the following specific and operational objectives:

- The ability to create and keep jobs by means of tourism-related activities
- The increase of added value within tourism activities;
- The creation, improvement and diversification of touristic infrastructure and services;
- The increase of the number of tourists and their visit duration;
- The enrichment and improvement of low-scale tourist reception structures;
- The development of tourism-related information and promotion systems;
- The erection of recreational facilities designed to ensure access to natural areas of touristic interest.

In order to obtain EAFRD funding, beneficiaries eligible to receive support, as per measure 313, are the following types of organisations:

- Micro businesses;
- Townships, through their legal representatives, according to the national legislation in force, as well as intercommunity development associations
- NGOs

- Also, physical persons who are not registered as business operators, and who undertake to officially acquire at least a self-employed person's status and operate as a micro business

Eligible beneficiaries wishing to access the funds allotted through NRDP may choose among the following eligible activities to guide their investment towards:

- Investments in the tourist reception infrastructure: extending, modernising, extending and fitting agricultural tourism and touristic structures according to the agreed upon standards;
- Investments in recreational activities: investments in the recreational tourism infrastructure, dependent upon or independent from the tourist reception structure;
- Investments in the small-scale infrastructure, such as information centres, the fitting of trails, etc.
- Investments related to the creation and outfitting of thematic routes (e.g.: "the wine road", "the pottery road", etc.).
- The development of marketing for rural tourism services: the elaboration of promotional materials, as well as informative and promotional websites.

For public interest investments which do not generate any profit, the public non-reimbursable support shall be up to 100% of the total eligible expenses and shall not exceed the amount of 200,000 Euro per project. For the other investments, the public non-reimbursable support is:

- 85% of the total eligible expenses and shall not exceed 100,000 Euro/project, in the case of agricultural tourism investment projects;
- 85% of the total eligible expenses and shall not exceed 200,000 Euro/project, in the case of investment projects for recreational activities;
- 50% of the total eligible expenses and shall not exceed 200,000 Euro/project or 70%, within the 70,000 Euro limit, for other types of investments in rural tourism.

Non-reimbursable funding for the construction of a new boarding house is granted only for land plots of at least 1000 sm. The land may be in ownership or leased. For the extension or modernisation of an existing boarding house this conditions shall not apply. In that respect, for the 2007-2013 programming stage, as per measure 313, item a), 813 projects amounting to 655,342,492 lei were carried out.

The Regional Operational Program

"The Regional Operational Program was launched on July 13, 2007, the same year when the documents related to the implementation of the projects were also completed. The general goal of ROP consists in supporting and promoting the durable local development, both from an economic, as well as a social standpoint, in Romania's regions, by optimising the infrastructure conditions and the business environment, which are the pillars of economic growth" (http://www.mdrap.ro/comunicare/presa/comunicate/regio-programul-operational-regional-conferinta-de-prezentare-a-raportului-anual-de-implementare-aferent-anului-2010). Investors who wish to locate lodging units in the urban area may also benefit from non-reimbursable funding from the European Regional Development Fund, respectively, though the Regional Operational Program, as part of the Priority Axis 5 - Sustainable development and tourism promotion, Key Area of Intervention 5.2 - Creation, development, modernization of the tourism infrastructure for sustainable valorisation of natural resources and for increasing the quality of tourism services. The total value of a project carried out through ROP must be between 700,000 lei and 89,000,000 lei, and for projects to be implemented in rural areas the minimal total project value must exceed 6,400,000 lei. ROP shall finance those touristic potential sights included in urban localities, in rural localities where projects whose value exceeds 6,400,000 lei and in balneary and health tourist resorts, whereas eligible expenses refer to:

- Investments in the tourist reception infrastructure (construction, modernisation, extension and fitting);
- Investments in recreational activities;

- Investments in the low-scale infrastructure, such as information centres, the fitting of trails, etc.;
- The development of marketing for rural tourism services.

The specific objectives of ROP for Key Area of Intervention 5.2 are the following:

- The capitalisation on natural resources for touristic purposes;
- The diversification of tourism-related services;
- The creation / extension of touristic recreational structures, intended to increase the number of tourists and the duration of their stay;

The SMEs undertaking touristic and related activities, in accordance with the National Classification of Economic Activities (CNAE), are bodies eligible to access non-reimbursable European funds. ROP shall finance all SME categories in the field of tourism, except for micro businesses implementing projects which do not exceed 1,500,000 Euro, located in rural area resorts, save for those situated in balneary and health resorts, which are funded from NRDP. The applicant's own minimal contribution to the eligible project value amounts to:

- for the public use tourism infrastructure: 1.94%
- for the public/private tourism infrastructure, which fall under the rules of state aids: between 30 and 60%, in accordance with the regional aid map for Romania 2007-2013, adopted by GD no. 946/ 2006 on the maximum threshold of the regional state aid for initial investments, and EC Commission Decision N-2/20072.

During the 2007-2013 programming stage, 135 projects were funded for the amount of 2,681,864,562 lei, taking into account the sustainable development principles conceived to diminish and minimise the environmental impact, complemented by the activities in the "Environment" Operational Program.

Conclusions

Tourism nowadays represents a strategic option for numerous national economies, due to its beneficial effects from an economic, social and cultural perspective and, respectively upon the natural environment, to a certain extent. From a social standpoint, a high share of the population is driven into the touristic circulation, since tourism satisfies a multitude of human needs - rest, recreation, knowledge, health care, relaxation, enrichment of one's cultural background, communication, adventure, etc., acting as both an important indicator of life quality, as well as a means to improve it.

Depending on its particularities, a touristic area appeals to investors by means of the opportunities provided for developing an efficient business. Thus, one may refer, on a global scale, to the existence of a complex and diverse offer designed to satisfy all of the tourists' tastes and financial possibilities. As a share, tourism represents the third socio-economic activity in the European Union, being estimated to generate around 12 % of the total work force. This translates into a positive impact upon economic growth and employment figures, as tourism accounts for an important sector, both for the EU citizens, as well as for its industry. Through its global nature and complex content, tourism currently drives vast material and human resources, with a profound aftermath in the evolution of the entire society. Tourism is the main industry when it comes to the contribution to the gross world product, takes the first spot in the employment charts and operates as the most important capital investor, in which case the procurement of non-reimbursable European funds stimulates this economic sector in Romania, by increasing the number of tourist accommodation units and elevating their quality levels, and also by developing recreational opportunities in touristic areas.

A MapReduce-Based Approach for Continuous K-Nearest Neighbor Search in Road Networks

Abstract

This paper presents a new approach to the continuous K nearest neighbors search (C-KNN) problem, in the context of road networks. Our approach is based on Formal Concepts Analysis (FCA), which has a mathematical foundation. FCA offers an abstraction of the network based on the neighborhoods. We build the concept lattice based on the binary relations between the target points as well as their properties. The latter are collected from various sensors on the road network. An indexing phase is also defined to speed up the search process and to reduce the processing time. However, the fast increasing number of moving objects and the high dynamic nature of the road network pose a big challenge to the ck-NN search of moving objects. In this paper, we present a parallel search method to improve the efficiency by upgrading the MapReduce paradigm. A density-based road network partitioning approach is employed in our MapReduce based CkNN search. Finally, implementation based on the Storm parallel programming model is discussed to show the effectiveness of our FCA-based solution.

Keywords: K-Nearest Neighbors Queries, Spatial Road Network, Formal Concept Analysis, MapReduce.

1 Introduction

With the proliferation of wireless communications and positioning technologies (e.g. GPS-Global Positioning System), applications and location-based services (LBS) have emerged and rapidly have gained more attention. A major problem in LBS concerns the search of nearest neighbors (NN). For example, a user in his car searches for the nearest restaurants throughout his path. The response to this kind of queries must be valid at the time of receipt by the user.

So far, the search of the k nearest neighbors (k-NN) is a major problem in data warehouses including data that describe dynamic environments of moving objects. There are several techniques for processing K-NN search queries in a static data-environment. In (Roussopoulos et al., 1995), the authors propose a method for calculating the nearest neighbors in a R-Tree. An alternative based on Voronoi cells was proposed in (Berchtold et al., 1998). Other works (Korn at al., 1996; Seidl and Kriegel, 1998) propose to run through the data set, several times, until the shortest distance is reached. Recently, research has focused on continuous k-nearest neighbors search queries (C-KNN) of moving objects in the context of road network (Lee et al., 2009; Samet et al., 2008). A continuous query is a query that, instead of being processed only once at the moment of submission to the system, is continuously evaluated during a given time interval (Terry at al, 1992). With the absence of a standard processing such requests in a dynamic environment, several approaches have been proposed. The challenge is to provide users with valid responses upon receipt.

To meet our goals, formal concept analysis (FCA) seems to be an elegant solution to allow grouping interest points (i.e. moving objects) in a hierarchy of levels. Each level corresponds to a group of mobile objects that share a common set of properties (e.g., speed, position, direction, etc.). The adoption of FCA in various IT fields, such as knowledge extraction and representation (Lakhal and

Stumme, 2005), technologies related areas (Bendaoud et al., 2010) or databases (Rancz and Varga, 2008), has highlighted the importance of concept lattice structures.

Thus, we propose a novel approach to continuous k-NN search which is applied to the road network context. Our contribution is based on a mathematical technique, namely formal concept analysis, in order to present a network abstraction that is based on the neighborhoods. Our approach aims to meet user needs, while considering the road conditions and the user context.

However, the time spent to find the nearest moving objects will exceed the constraints for real-time execution. This also adds more complexity to the FCA-based search method as the complexity of parsing large concept lattice depends on the number of moving objects and the degree of changes in their properties. Thus, this problem becomes especially important and challenging as the number of moving objects in the road network increases.

Similar to most big data applications, the big data tendency also poses heavy impacts on CKNN search systems. Indeed a real road network (modeled as a Big complex graph) is composed of a very large set of nodes and their arcs. Each element is characterized by a set of static and dynamic properties (e.g. disturbance factors). Such properties need to be processed instantly in order to deliver the suitable response (near moving objects) to a user.

Existing methods still cannot support very large road networks (e.g. the whole USA road network). The main limitation of these approaches is either high memory consumption or heavy search overhead.

For example, for the whole USA dataset (24M vertices), we estimate that state-of-the-art approach like ROAD (Lee et al., 2009) needs over 105 days for pre-processing, and SILC (Samet et al., 2008) consumes approximately 618GB memory, which represents a very poor scalability and efficiency on large road networks.

In this paper, we combine the strengths of FCA and MapReduce to present a parallel continuous k-nearest neighbor (CKNN) search method of moving objects in road network and we improve the efficiency of located moving objects by employing the MapReduce paradigm. In particular, our main contributions can be summarized as follows:

- *Road network partionning.* We divide the road network into a set of smaller search spaces and deliver them to corresponding slaver servers to use their changing conditions in the selection of candidate moving objects.
- *MapReduce functions based of Formal Concept Analysis*. We show how the powerful mathematical method FCA is used to represent the data-related moving objects and to allow their clustering and effective parsing and search. In the *Map* function, we extract the near candidate moving objects according to their properties using FCA. In the *Reduce* phase, we merge the candidate moving objects and compute their shortest paths and distance based on their properties as well as the current road data.
- *Prototype implementation*. We show how a parallel programming platform called Storm is used to implement the FCA-based search method.

The rest of the paper is organized as follows: Section 2 presents our previous work. Section 3 gives an overview of the adopted technique. In Section 4, we present our parallel FCA-based approach to the search for k-nearest neighbors in a road network. Section 5 gives some details on the implementation and the performance evaluation of our kNN search approach. Section 6 summarizes the state of the art research methods of k-nearest neighbors in road networks. The last section is devoted to the conclusion and future work.

2 Previous work

In this section, we give an overview of our previous work (Ferchichi and Akaichi, 2015). In the first sub-section, we start by presenting the Formal Concept Analysis mathematical formalism, we have

adopted in our continuous k-nearest neighbor search method approach. The second sub-section presents the main steps of the proposed FCA-based search method.

2.1 Formal concept analysis

Formal Concept Analysis (FCA) is a mathematical formalism that provides hierarchically structured concepts and group objects having the same attributes. The resulting hierarchy of the FCA is known as Galois (Barbut and Monjardet, 1970) or concept lattice (Ganter and Wille, 1999). The mathematical foundation of FCA and conceptual structures that can be derived (Godin et al., 1995) have been exploited in several areas, such as classification and information retrieval (Carpineto and Romano, 2005), Web service selection (Azmeh et al., 2008), ontology construction (Bendaoud et al., 2010), knowledge extraction (Lakhal and Stumme, 2005), software engineering (Tilley et al., 2005) and (Godin and Valtchev, 2005), linguistics (Priss, 2005), etc. FCA allows building a concept lattice from a binary relation Objects X Attributes (see the next sub-section).

Definition 1 (Formal Context): A Formal Context is a triplet K = (G, M, I) where G is a set of objects, M is a set of attributes and I a binary relation between G and M satisfying: $I \subseteq G \times P$; $(g, m) \in I$ with $g \in G$ and $m \in M$, g means that the object has the attribute m or m is an attribute possessed by the object g.

Definition 2 (Formal Concept): A Formal Concept of a context K = (G, M, I) is a pair (A, B): $A \subseteq G$, $B \subseteq M$, A' = B and B' = A, where A' is the set of all attributes of B possessed by the objects of A and, in a dual way, B' is the set of all objects having the attributes of B. The sets A and B are called respectively extension (Extent part) and intension (Intent part) of formal concept C. B (G, M, I) denotes the set of all concepts of the context K = (G, M, I).

2.2 FCA-based continuous k-nearest neighbor search in road networks

A graph is a suitable candidate to model a road network. As shown in Fig. 1, a graph-based road network, which is considered as the search space, consists of vertices (nodes) that are connected by links (roads connecting the various nodes). The graph contains several static information (edges and nodes) and dynamic information (moving objects together with their characteristics).

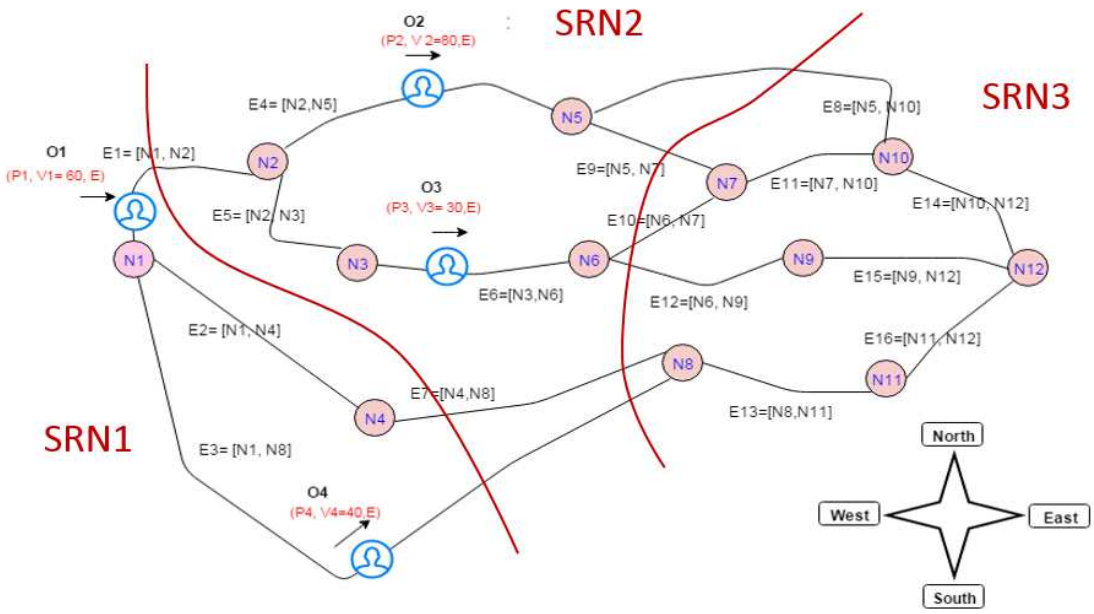

Fig. 1: Research space at time t = 0

Our FCA-based CKNN search method takes as input a graph-like road network and a set of candidate moving objects with their static and dynamic properties. It consists of the four main steps, described as follows:

- **Step 1 (road network modeling).** The search space or the road network is modeled as a graph G. The aim of the first step is to transform the road network to an abstract graph G. G is composed of a set of nodes *N* and edges *E*. The latter carries several information: static information (nodes and edges) and dynamic information (moving objects and their characteristics).

- **Step 2 (Formal context extraction).** In our work, the characteristics of moving objects will be delivered in real time to our system. Based on the road information, and on the different characteristics of the moving objects, this step, first, performs the binarization of the moving objects' characteristics, then the generation of the matrix of formal context from the information extracted from the graph-based road network. We denote by O all the moving objects, and by A the set of their attributes (characteristics of moving objects).

- **Step 3: (Generation of the lattice of moving objects).** This step takes as input the formal context created in step 2, and generates a lattice of candidate points of interest. Each formal concept in the lattice represents a candidate solution to a given search query. To reduce the time spent in the search within the lattice of moving objects, we propose to index all the concepts in the lattice based on what we call "level of concept". A level is defined for each generated concept. An index table will be created (Level + concepts) in order to accelerate the search process.

- **Step 4 (Query Evaluation or answering).** This step consists of searching within the generated lattice in order to extract the relevant formal concepts. This allows retrieving the moving objects that can satisfy the user's query.

The use of FCA for searching the k-nearest neighbors is motivated by two main features: the conceptual structure of the lattice data and the hierarchy between the concepts. The complexity of lattice construction depends on the number of moving objects and their properties. The construction of concepts is equal to O(k.m), where k is the number of properties of an interest point, and m is the number of points of interest. The complexity of the search algorithm is equal to O(L) where L is the number of concepts. However, maintaining the relevance of the delivered results mainly depends on reducing the response time, because these results must be valid at the time of their receipt by the user. To achieve our goals, the proposed approach aims to reduce the search space and the response time by parallelizing the search task. This is achieved with the use of MapReduce parallel programming parading as we will show in the following sections.

3 MapReduce parallel programming model

In this section, we first describe the basics of MapReduce programming Model. MapReduce is a framework proposed by Google to allow processing highly distributed problems across huge datasets using large number of computers. The distribution of the large amount of data implies parallel computing since the same computations are performed on each CPU, but with a different dataset.

In a MapReduce job, the master node first partitions input data into M independent chunks (where M is the number of Map tasks) and passes them to the mapper nodes. Each map task is independently executed in a mapper node. Afterwards, in the map phase, each mapper generates a series of intermediate key–value pairs based on the input data chunks and according to a user-defined Map function. The MapReduce runtime system then automatically sorts and merges these intermediate key–value pairs depending on the key. The intermediate data with the same key are divided into R segments (where R is the number of reducer nodes) using a hash function. Finally, after being notified of the location of the intermediate data in the reduce phase, each reducer accepts a set of intermediate key–value pairs and merges all the data with the same key value, then generates a series of key–value pairs according to a user-defined Reduce function (Li et al., 2015).

4 Proposed approach

In this section, we present the proposed framework for continuous k-nearest neighbour search in road networks with MapReduce (see Fig. 2).

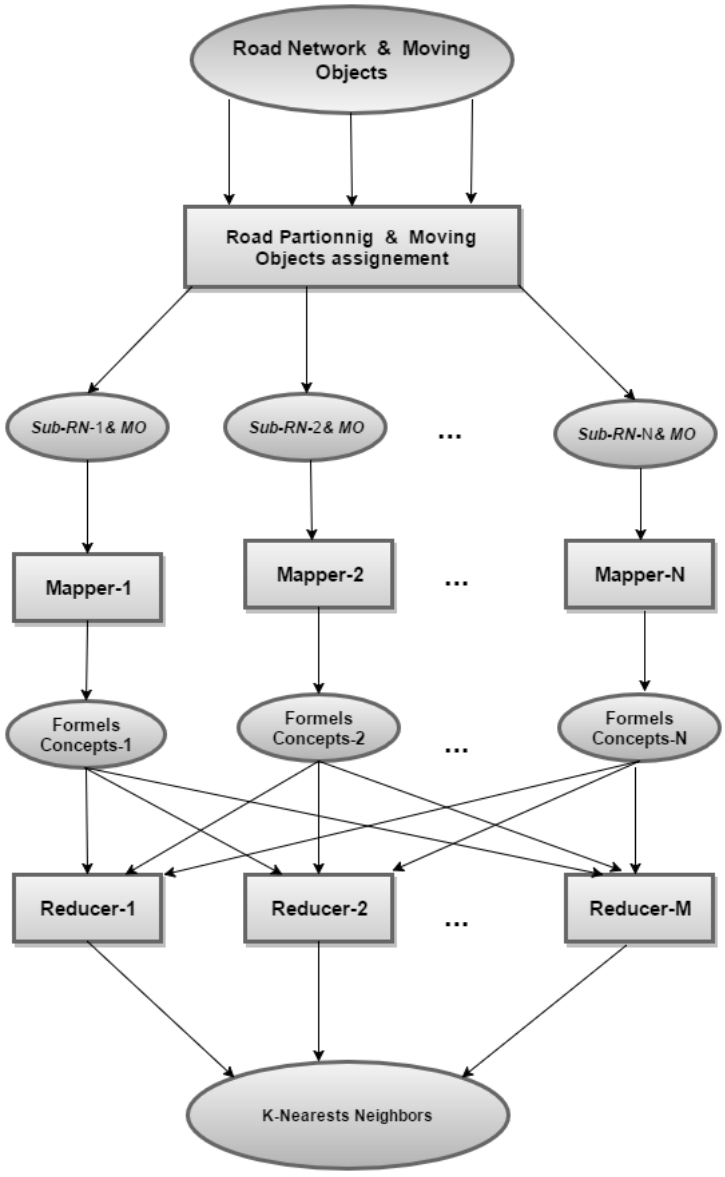

Fig. 2: A system overview of the CKNN search approach. In this figure, ellipses represent road network data, squares represent processing of candidate moving objects and rows show the flow of data.

As shown in Fig. 2, our CKNN search method works as follows:

1. Input road network is partitioned into *N* sub-road networks. Each sub-road network will be processed against the user query by a mapper machine, in order to evaluate the network state and the candidate moving objects that belongs to this sub-road network.

2. Mapper *i* reads the assigned sub-road network partition and returns the corresponding candidate moving objects that meet the user query. Mapper *i* outputs key/value pairs of near moving objects. *Keys* represent properties of moving objects, whereas *values* represents moving objects.

3. For each unique intermediate key, the reducer passes the key property and the corresponding set of intermediate values (near moving objects) to the defined reduce function. According to these key/value pairs (in our case properties/candidate moving objects), the reducer outputs the final list of key/value pairs of the k-nearest moving objects after filtering according to the user requirements, and the feasible solutions.

The next sub-sections give more details about each of the above steps.

4.1 Density-based road network partitioning method

The motivation behind dividing the road network data into sub-road networks is to reduce effectively the search space by dealing with small graphs of roads. This allows searching the k-nearest neighbors in parallel fashion. Finally, the intermediate results are combined to get the k-nearest moving objects. Using this approach, we can decrease the complexity of our previously proposed FCA-based search method (Ferchichi and Akaichi, 2015), as the time complexity of the search process is proportional to the size of the formal context and the concept lattice of candidate moving objects.

However, it is important to adopt an effective partitioning technique to avoid the loss of road network and moving objects information. In addition, the arbitrary partitioning method of MapReduce may be the origin of map-skew which refers to imbalanced computational load among map tasks (Kwon et al., 2012) and consequently to the non-satisfaction of user requirements.

In addition, there is a big difference in the distribution of moving objects across the search space. Non-uniform distribution of moving objects would cause many problems. For example, query response time difference among different areas would lead to difficulties in decision-making. To solve non-uniform distribution problems, we need an intelligent region dividing method to ensure the efficiency of query in different areas and to improve the quality of delivered response.

Considering the fact that the task of CKNN search depends on the road network state and its complexity in terms of roads (considered as arcs in the graph-based modelling), we adopt the density-based method proposed by (Aridhi et al., 2015). The proposed method consists of constructing partitions (chunks) according to the density of graphs. The goal behind this partitioning is to ensure load balancing and to limit the impact of parallelism and the bias of tolerance rate. The following definitions are used:

Definition 3 (Graph). A graph is a collection of objects denoted as G = (*V, E*), where *V* is a set of vertices and $E \subseteq V \times V$ is a set of edges. A graph G' is a subgraph of another graph *G*, if there exists a subgraph isomorphism from G′ to G, denoted as $G' \subseteq G$.

Definition 4 (Sub-road network). A graph-based Sub-road network G’ = (V’, E’) is a sub-graph of another graph (the whole road network) G = (V, E) iff V’ ⊆ V and E′ ⊆ E.

Definition 5 (Graph density). The graph density measures the ratio of the number of edges compared to the maximal number of edges. A graph is said to be dense if the ratio is close to 1, and is said to be sparse if the ratio is close to 0. The density of a graph G = (V, E) is calculated by

$$density(G) = 2.\frac{|E|}{(|V|.(|V|-1))} \quad (1)$$

Table 1 shows the density results of partitioning the graph-based road network. The partition of sub-road network *SRN3* is smaller than those of *SRN1* and *SRN2* because of the possible alternatives offered to a moving objects in terms of roads (i.e. arcs).

Table 1: Density example of the three sub-road networks

Sub-road network	Density
SRN_1	0.25
SRN_2	0.5
SRN_3	0.6

Based on the results of the partitionning step, the moving objects and their characteristics are represented in three Formal Contexts according to the number of Sub-road networks. Consequently, three mappers are responsible for the search task within the generated formal contexts, in ordr to extract the near candidate moving objects.

Due to the space limit in the paper, we only present an example of formal context and lattice derived from the first sub-road networks (see Fig. 3 and Fig. 4).

		Characteristic's of Mobiles Objects														
		Velocity					Direction				N-Direction ()		Edge	Path ()	Statut( )	
		V1	*V2*	*V3*	*V4*	*V5*	*North*	*South*	*East*	*West*	*SD*	*RD*	*Fp(P[MO])*	*Same-Path ( )*	*Near*	*Far*
Mobile Objects	*MO-1*	0	1	0	0	0	0	0	0	1	0	1	0	1	1	0
	MO-2	1	0	0	0	0	0	0	1	0	1	0	0	0	1	0

	MO-10	0	0	1	0	0	0	1	0	0	0	1	0	1	1	0

Fig. 3: Formal context of the moving objects assigned to the 1st mapper

Next, we present the tasks of the Map and Reduce functions for processing the formal context and searching the k-nearest neighbors through the lattice of moving objects.

4.2 FCA-based MapReduce functions

In this phase, we apply our FCA-based CKNN search method that we run it on each sub-road network in parallel. Algorithm 1 and 2 present our Map and Reduce functions respectivelly.

FCA-based Map function. In the Map function, the input key/value pair would be like <i, FC_i>, where *i* corresponds to the i^{th} partition of the road-network, and FC_i is a formal context representing a set of candidate moving objects at a time *t*.

As shown in algorithm 1, the formal context FC_i associated to the i^{th} mapper is transformed into a concept lattice L_i of moving objects (line 1). For the construction of the lattice, we use one of the existing algorithms (e.g. Bordat, Next Neighbor) offered with the Galicia (http://www.iro.umontreal.ca/~galicia/) tool. The lattice constructed by the first mapper is shown in Fig 5. Then, for each concept C_j in the lattice L_i, the mapper checks the status of each candidate object (lines 2 and 3), so that it can outputs the key/value pairs of near objects (line 4).

Algorithm 1. Map function

Require A Sub-road network graph, a user query, a formal contect FC_i
Ensure key/value pairs of near candidate moving objects
1: $L_i \leftarrow$ BuildMovingObjectsLattice (FC_i)
2: for each Concept Cj in L_i
3: **if** MOStatut(Cj.Intent) = near **then**
4: EmitIntermediate(Cj.Intent, Cj.Extent)
5: **end if**
6: end for

The output key/value pairs of the Map function would be like <P, MO>, where *P* is a set of properties characterizing a set of moving objects, and *MO* corresponds to the candidate objects that are characterized by the properties *P* at a time *t*.

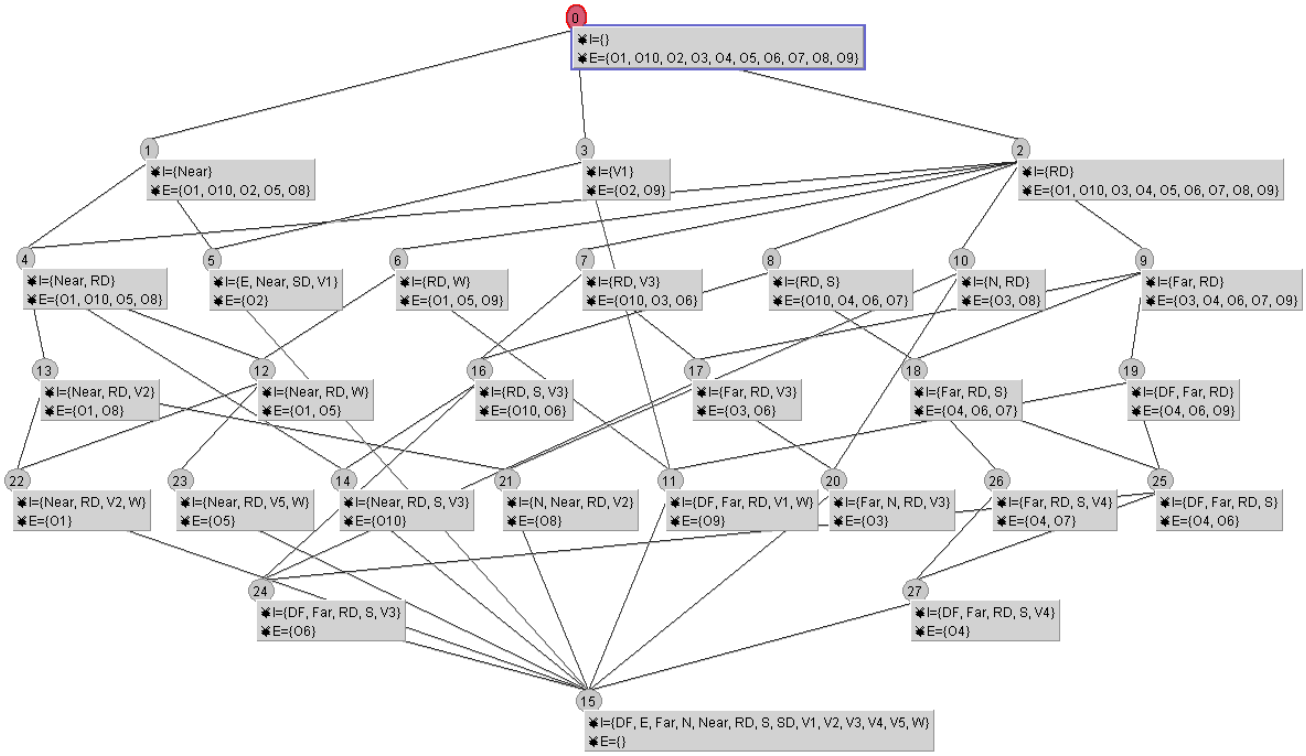

Fig. 4: Generated Concept Lattice of Moving object for the 1st mapper

After searching within the lattice constructed by each mapper, the output key/value pairs of all the Map functions (see Fig. 5) are then processed in the Shuffle phase and grouped together by key (i.e. characteristics of moving objects). Finally, one node is chosen to calculate the distance and the shortest path to the candidate moving objects that share the same properties. Note that this phase is out of the scope of this paper, as the movement of data is transparently orchestrated by the adopted MapReduce framework (see section 5).

Mapper 1		Mapper 2		Mapper 3	
Key	Value	Key	Value	Key	Value

Fig. 5: Key/value pairs' outputs of the Map phase

FCA-based Reduce function. The shortest path problem in real-road networks is the cornerstone of the reduce phase in the CKNN search process. The reduce function receives a set of pairs <P, MO> that represent the near moving objects (results of the FCA-based Map function after eliminating the far moving objects). The reduce function, then, computes the distance and the shortest path to each near candidate object. Only near objects that have a distance smaller than a given threshold (specified by the user) will be kept.

In the Reduce function, the input key/value pair would be like <P, MO>. The Reduce function outpouts a sorted list of moving objects according to the calculated distances. We use the distance between the query point and a candidate moving object as a key in the outpouts of the Reduce function (see Algorithm 2).

To compute the shortest distance between the query point and each candidate near moving object, we adapted Dijkstra algorithm. According to Denardo [29], Dijkstra algorithm is the most time efficient algorithm for computing shortest path. Complexity of the computation time is O(nm log(n)), where *n* is the number of nodes in the graph-like road network and *m* the number of outgoing arcs of the graph.

The procedure *ShortestPathComputation* is based on Dijkstra's algorithme. It takes as input a query point *QP* and a candidate moving object *MO*. The procedure output is a shortest path from *QP* to *MO*, with its corresponding distance. The distance is defined by its origin (QP_x, QP_y) and destination (MO_x, MO_y) positions. Note that the distance and path computation is not realized on a separate sub-graph of the road network, bu on the initial road network.

Algorithm 2. Reduce function

Require A set of key/value pairs
Ensure key/value pairs of candidate moving objects, key = P, Pair = MO
1: for each MO **do**
2: Pth ← ShortestPathComputation (P, MO)
3: D ← ComputedDistance(Pth)
4: EmitIntermediate(D, Pth)
5: end for

As shown in the above algoritm, the reducer starts by calculating, for each near moving object, the distance *D* and the shortest path to the each moving object (lines 2 and 3). Since, several pairs may have the same distance with the query point, the reducer sorts them by distance and according tot he number of nodes in the selected path. Finally, the reduce function returns output key/value pairs in

the form of <D, Pth>, where *D* is a distance in *km* with respect to a minimum threshold, and *Pth* corresponds to shortest path between the query point and the candidate objects MO.

Following is an example of reduce function's output:

<5.4; {N1, N5, N9, N10, N12}>

Here the key *5.4* is the distance in km whereas the value *{N1, N5, N9, N10, N12}* represents a shortest path composed of five nodes.

The final output of this CKNN search process in the road network is an ordered list of the k-nearest neighbors and their positions in the corresponding sub-road network.

In the next section, we present the implementation details of our FCA-based CKNN parallel search approach.

5 Implementation and parallel CKNN search settings

The implementation of our prototype consists of three phases: (1) the extraction of the formal context, (2) the generation of the lattice of moving objects, and (3) the search of interest points within the generated lattice. Our prototype is implemented with the Java language.

To improve its scalability and efficiency in big data environment, our prototype is implemented on Storm (Toshniwal et al., 2014), a widely-adopted distributed computing platform using the MapReduce paradigm. We choose this plateform between other dominant open-source MapReduce frameworks such as Apache Hadoop (http://hadoop.apache.org/) and Spark (http://spark.apache.org/).

Apache Storm is an open source and a fault tolerant framework for processing large data in real time. Storm allows real time data analysis, machine learning, sequential and iterative calculation. It is characterized by its simplicity, scalability and speed of calculation. More precisely, it processes the data in the order of one million tuples per second for each cluster nodes. Following a comparative study of Storm and Hadoop, we find that the first is geared for Big Data applications in real time while the second is effective for batch applications. Also, Hadoop stores its data in the HDFS and thus does not allow iterative computation, whereas Storm allows different resources and iterative computation. Storm use the key-value format and support streaming mode (contrarily to Haddop which processes the data in batch mode), which is suitable to the case of continuous search of moving objects with changing properties (e.g. speed, position, etc.) in road networks with dynamic states.

Based on this comparison, we implemented the parallel FCA-based search search algorithm using Storm because it is suitable for real time applications.

Regarding the evaluation of the accuracy and scalability of FCA-based CKNN search, to see the impact of the number of moving objects on the complexity of lattice construction and k-nearest neighbors' extraction, extensive experiments are conducted. We have varied the number of moving objects (between 500 and 4000) in a road network graph containing 500 nodes (see Fig 6).

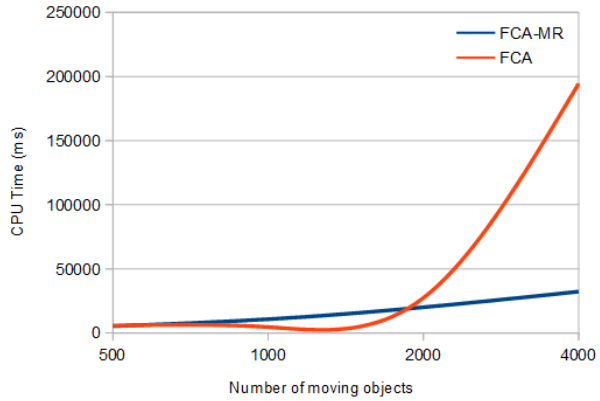

Fig. 6: FCA based search vs FCA-MR based search

Compared to the FCA-based search method, the parallelization of the search (FCA-MR) task significantly reduced processing time. This is explained by the partitioning of the unique context (used in FCA-based method) into a set of formal contexts with reduced sizes (in FCA-MR method). Therefore, the lattice constructed from each small formal context is processed in an acceptable time and, hence, complexity is reduced.

Moreover, partitioning the road network graph also reduced the search space (500 nodes in the case of the FCA-based method) unlike our FCA-MR approach, which allows browsing small sub-graphs (e.g. 125 nodes in the case of the first Mapper).

Fig. 6 also shows that, when the number of moving objects exceeds 2000, our FCA-based method is no longer able to return a valid response in a reduced time which violates one of the major constraints in the continuous k-nearest neighbor research problem. The integration of MapReduce logic into our FCA-based method has allowed delivering a valid response within an optimal (see case of 4000 moving objects).

To ensure that the FCA-MR method maintains an acceptable level of performance even in large scale CKNN problems and to ensure that the processing time will not be affected by the increase in the size of formal contexts, we conducted another series of test by varying the number of moving objects from 5000 to 10000 (see Fig. 7).

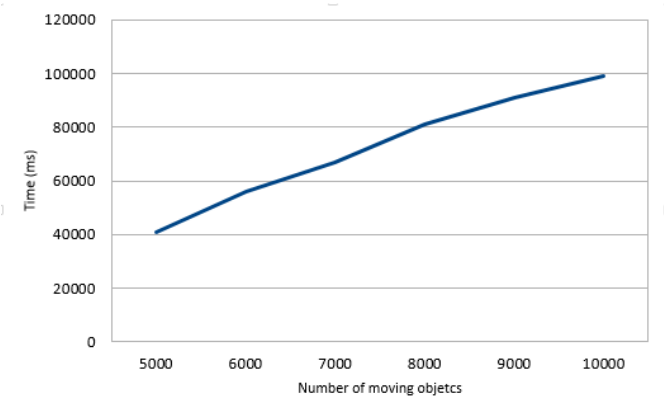

Fig. 7: FCA-MR performance with large number of moving objects

As shown in the Fig. 7, the increase in the number of moving objects did not affect the performance of our FCA-MR method. This is explained by the logic of allocating Map and Reduce tasks in Storm. A suitable configuration of blocks' size in Storm may guarantee the partitioning the formal context in small portions of formal contexts.

6 Related work

To resolve the kNN search problem, several approaches have been proposed. The most common classification of this problem is based on the way the distances between points are calculated, including Euclidean distance and the distance of shortest path.

Multidimensional indexing techniques have been studied extensively such as the R-tree (Guttman, 1984). Several variants of the R-Tree appeared among them R * Tree (Beckmann et al., 1990) or the X-Tree (Berchtold et al., 1997). These indexing structures have shown their limits in case of higher dimensions. The work proposed by (Song and Roussopoulos, 2001) suffers from the quality of results, as it highly depends on the number of examples as input. If the number of examples is small, the result will be wrong. In (Khyati and Akaichi, 2008), Delaunay triangulation is used for modeling a road network consisting of direct routes joining points of the space. The authors propose to apply a partitioning model in the road search space, by adding weighting factors such as urban traffic, elapsed time, velocity.

Recent attempts, such as (Zhong et al., 2013) which propose an index G-tree to find the k-NN at a given location, have shown limitations relative to the size of the studied network.

Most of the above discussed approaches showed shortcomings and are, in most cases, unable to satisfy the users, especially in case of large dimensions or in case of dynamic context. However, the relevance and effectiveness of the expected results depend heavily on the way the search space is indexed and on the research methods used in these indexes structures.

MapReduce-based approaches. Recently, the MapReduce parallel programming model has been applied to resolve the kNN problem (Stupar et al., 2010; Yu et al., 2015; Zhu et al., 2015; Ji et al., 2013; Lu et al., 2012). However, they cannot be directly applied to the problem of k-NN search over moving objects, as they suffer from large preprocessing and update costs.

(Akdogan et al., 2010) presented a distributed Voronoi index and techniques to answer three types of geospatial queries including reverse nearest neighbor (RNN), maximum reverse nearest neighbour (MaxRNN) and k nearest neighbor (kNN) queries. The location of a point in Voronoi takes extra time. It also incurs high maintenance cost and computation cost when the dimension increases.

SpatialHadoop (Eldawy, 2013), is a MapReduce framework that aims to support k-NN spatial queries. However, it is not suitable to the processing of continuous k-NN queries, since it is not specifically designed for moving objects and because the MapReduce paradigm employed by SpatialHadoop is a batching-oriented processing paradigm and is not good at handling the incremental changes to the query results caused by numerous small updates. SpatialHadoop does not consider the maintenance cost explicitly, and the index may not work well in the presence of frequent position updates.

Based on the above discussions, our work aims to resolve the majors issues related to exploring the search space as well as reduce the time spent to deliver a response to the user. This is achieved by combining the strengths of Formal Concept Analysis, as a powerful mean of clustering the moving objects–related information's, and the processing capabilities of MapReduce, as a well-known parallel programming model.

7 Conclusions and future work

In this paper, we have proposed an approach to the continuous k-nearest neighbor search in road networks using a synergy between Formal Concept Analysis and MapReduce parallel programming model. The proposed method relies on a density-based partitioning technique that considers road network characteristics. It uses the densities of roads in order to partition the search space. Such a partitioning technique allows a balanced computational load over the distributed collection of machines and replaces the default arbitrary partitioning technique of MapReduce.

The proposed method allows creating, from a partitioned graph-based road network, a set of formal contexts to be used in the construction of the corresponding concept lattices. These later represent the hierarchy of characteristics of the candidate moving objects. Once built, the step of searching points of interest in each lattice can be performed by a set of Mappers in a parallel fashion, through a classification scheme offered by the generated lattice of moving objects. Finally, the extracted concepts in the map phase are processed by the Reducers in order to return the nearest objects.

The mathematical foundation of FCA method has ensured a high level of accuracy and trust in the delivered answers. Also, the MapReduce framework was used to effectively deal with the highly distributed CKNN search problem across huge number of moving objects.

In the future work, we will study the influence of disturbance factors (e.g. traffic jam, accident) on the quality of delivered responses. We, also, intend to validate our approach through a set of experiments.

Abstract

Overall objective related to public health in the European Union (EU) Sustainable Development Strategy (SDS) is to promote good public health on equal conditions and improve protection against health threats. The satellite accounts provide the opportunity of making connections between non-monetary statistics and the standard framework of the national accounts. The functional satellite accounts allow new concepts and methods which are characterized by a higher degree of freedom than those in the main national accounts system. When designing and compiling a satellite account, applying the concepts of the main framework for a specific purpose often results in the discovery of certain characteristics. This concept is also applicable in the case of health satellite accounts. Our results clearly demonstrated that, from the point of view of their aim, these characteristics may be helpful, but they can also present previously unforeseen limitations, especially in particular cases as Romania.

Keywords: national accounts system, health satellite accounts subsystem, European Union, Romania.

Introduction

Article 152 of the Treaty establishing the European Community states that 'a high level of human health protection shall be ensured in the definition and implementation of all Community policies and activities', thus acknowledging that public health is heavily dependent on policies in many other areas, including environment, agriculture, industry, trade, and social and economic policy.

The current version of the EU health strategy developed by European Commission (2007) presents three strategic themes intended to meet the major challenges facing health in the EU. The first theme focuses on the promotion of healthy lifestyles to improve healthy ageing. The second, concerned with the protection from health threats, is an explicit objective in the Sustainable Development Strategy (EU SDS) and covers related subjects such as food security and environmental pollution. The third looks at the sustainability of health systems and the role of technological development in improving their efficiency.

At an operational level the health strategy is supported by the Second Programme of Community Action in the Field of Health 2008-2013, as stated by European Parliament (2007). This program supports over 3 000 projects and other actions with the following overall objectives: to improve citizens' health security, to promote health, including the reduction of health inequalities, and to generate and disseminate health information and knowledge.

Gathering and assessing accurate, detailed information on health issues is vital for the European Union to effectively design policies and target future actions.

Overall objective related to public health in the EU Sustainable Development Strategy is to promote good public health on equal conditions and improve protection against health threats. The operational objectives and targets are represented by: improving protection against health threats by developing capacity to respond to them in a co-ordinated manner; further improving food and feed legislation, including review of food labeling; continuing to promote high animal health and welfare standards in

the EU and internationally; curbing the increase in lifestyle-related and chronic diseases, particularly among socio-economically disadvantaged groups and areas; reducing health inequalities within and between the Member States by addressing the wider determinants of health and appropriate health promotion and disease prevention strategies (actions should take into account international cooperation in forums like WHO, Council of Europe, OECD and UNESCO); ensuring that by 2020 chemicals, including pesticides, are produced, handled and used in ways that do not pose significant threats to human health and the environment (in this context, the rapid adoption of the Regulation for the registration, evaluation, authorization and restriction of chemicals (REACH) will be a milestone, the aim being to eventually replace substances of very high concern by suitable alternative substances or technologies; improving information on environmental pollution and adverse health impacts; improving mental health and tackling suicide risks as stated by European Commission (2009).

Satellite Health Accounts in European Union

For the EU Member States, the European Accounts System **(**EAS) is the standard for submitting national accounts data to international bodies. The strict adherence to the EAS is mandatory only in national publications as stated by European Parliament (1997). The EAS concepts are focused on describing the economic process in easily observable monetary terms. The EAS concepts are, in all respects, consistent with the standards established throughout the world in the national accounting, namely the National Accounting System (NAS). The international compatibility is essential for statistics comparisons between countries.

For some specific needs in terms of data, the best solution is to have separate satellite accounts. These needs relate to data requirements for: the analysis of the role the tourism plays in the national economy, the analysis of the cost and financing of the health care, the analysis of the importance of the research and development (R&D) and the human resources for the national economy, the analysis of revenue and expenditure for households taking into account the microeconomic concepts of income and expenditure, the analysis of the interaction between the economy and the environment, the analysis of the production within households, the analysis of the changes in citizens' welfare, the analysis of the differences between the national accounts and the business accounts and their influence on stock and exchange markets, the estimation of tax revenues. Besides, there has been recently introduced the satellite accounts for the social economy as underlined by Costuleanu et al (2011).

Information about healthcare systems and, ultimately, about the health of a population is a prerequisite for monitoring the performance of health policy. The regional indicators currently available for health provide an insight into similarities, particularities and contrasts across regions in Europe. There can be big differences between regions in the same country, while regions in different countries may be very similar. Thorough analysis of trends and variations in health indicators at regional level is therefore indispensable for planning and monitoring action and programmes, formulating new policies, developing new strategies and, all in all, contributing to 'evidence-based health policy'. Costuleanu (2010) mentioned that Eurostat's work on health statistics is focusing mainly on further improvements in the quality, comparability and completeness of the data and further extension of the regional coverage.

The overall aim of a European health information strategy should be to provide information and analysis for evidence-based development, implementation and evaluation of action for health in the EU, at both Community level and within Member States. European health information can provide added-value through information enabling comparisons in particular, which can in turn support identification, dissemination and application of best practice as stated by European Commission (2009).

Effective knowledge management for health information requires more than generating information, such as data or indicators at European level. It also requires mechanisms for providing analysis and highlighting possible areas for action, exchanging and disseminating information in an appropriate way to people who can make use of it; and then supporting and monitoring the application of information in practice. A great deal has already been done with regard to generating information at Community level, and this should be brought together in an overall map of progress so far. Though

more will be needed, it should also now be complemented by a greater focus on analysis, dissemination and application of European health information as underligned by Costuleanu (2011) as well as by Costuleanu and Codreanu (2011).

European Commission (2009, 2011) established the main indicators used to assess the European health information, representing the basis of EU satellite health accounts are as follows:

-Healthy Life Years (Eurostat, 2016)
The Healthy Life Years (HLY) indicator (also called disability-free life expectancy) measures the number of remaining years that a person of a certain age is still supposed to live without disability. Healthy Life Years is a solid indicator to monitor health as a productivity/economic factor. Healthy Life Years introduces the concept of quality of life. It is used to distinguish between years of life free of any activity limitation and years experienced with at least one activity limitation. The emphasis is not exclusively on the length of life, as is the case for life expectancy, but also on the quality of life.

HLY is a functional health status measure that is increasingly used to complement the conventional life expectancy measures.

Any loss in health will, nonetheless, have important second order effects. These will include an altered pattern of resource allocation within the health-care system, as well as wider ranging effects on consumption and production throughout the economy. It is important for policy-makers to be aware of the opportunity cost (i.e. the benefits forgone) of doing too little to prevent ill-health, resulting in the use of limited health resources for the diagnosis, treatment, and management of preventable illness and injuries.

-Deaths due to chronic diseases (Eurostat, 2016)
Data on deaths by cause are usually based on the underlying cause, derived from the certifier's entries in parts I and II of the death certificate. Acceptable causes of death are those listed in the World Health Organization's (WHO) International Classification of Diseases (ICD). All EU countries use either the ninth or the tenth revision of the Classification. Data on causes of deaths are collected by Eurostat (at national and regional NUTS 2 level).

-Unmet needs for healthcare (Eurostat, 2016)
Good health is an asset in itself. It is not only of value to the individual as a major determinant of quality of life, well-being and social participation, but it also contributes to general social and economic growth. Many factors influence the health status of a population and these can be addressed by health policies regionally, nationally or across the EU.

Barriers to accessing health services include cost, distance, waiting times, lack of cultural sensitivities and discrimination. For non-native speakers, language can be an obstacle for those seeking to access services, while barriers to health care may result from poor understanding or a lack of knowledge with respect to a patient’s rights and the administrative practices and requirements of health systems.

The frequency of reporting unmet needs for medical care for reasons of expense decreased with increasing income. At the same time, the frequency of reporting unmet needs for medical care for reasons of high expense, too far to travel or waiting lists increased with decreasing educational attainment.

Generally, Member States with high shares of unmet needs for medical care due to being too expensive, too far to travel or waiting lists displayed particularly high shares for older people

-Production of toxic chemicals (Eurostat, 2016)
The indicator is a Sustainable Development Indicator (SDI). It has been chosen for the assessment of the EU progress towards the targets of the Sustainable Development Strategy.

The EU-28 production of toxic chemicals (all five toxicity classes together) increased by 0.5 % between 2004 and 2007 to reach a peak of 235 million tonnes. Production fell by 20 million tonnes in 2008 (or by 8.4 %) and by the same amount in 2009 (or 9.3 %) to a level of 195 million tonnes. The rebound in activity in 2010 (up 11.7 %) made up for the losses recorded in 2009 but was followed by

further reductions in 2011 (-5.0 %). Since then production of toxic chemicals is almost constant. As a result of these developments, the EU-28 level of production of toxic chemicals in 2014 was 206 million tonnes, almost 30 million tonnes less than in 2004.

-Suicides (Eurostat, 2016)
There are big discrepancies between suicide rates in different EU Member States (Figure 13). The yearly rates range from 3 deaths per 100,000 in Greece to 24 deaths per 100,000 in Finland.

Some of the variations in suicide across Europe may be due to differences in the process of death registration. Procedures for recording a death as a suicide are not uniform. Countries like Luxembourg require a suicide note in order to register a death as suicide, while in the United Kingdom an assessment of intent is required by a Coroner. Cultural and social norms also play a role in death registration. In cultures in which suicide is particularly stigmatised, it may be more common to record the cause of death as of undetermined intent or to record another cause.

-Exposure to air pollution by particulate matter (Eurostat, 2016)
The indicator shows the population-weighted concentration of PM10 and PM2.5 to which the urban population is potentially exposed.

Fine and coarse particulates (PM10) are those whose diameter is less than 10 micrometres, whilst fine particulates (PM2.5) are those whose diameters are less than 2.5 micrometers. Particulates can be carried deep into the lungs where they can cause inflammation and a worsening of the condition of people with heart and lung diseases. The smaller the particles the deeper they travel into the lungs, with more potential for harm. According to the recommendations of the World Health Organisation (WHO) the annual mean concentration is the best indicator for PM-related health effects.

The Directive 2008/50/EC set a framework to define and establish objectives for ambient air quality and to harmonise methods and criteria among the Member States. This does have limits for PM2.5. The limit value that was due to be met on 1 January 2015 is 25 µg/m3, which falls to 20 µg/m3 by 2020.

-Exposure to air pollution by ozone (Eurostat, 2016)
The indicator shows the population-weighted concentration of ozone to which the urban population is potentially exposed.

The principle metric for assessing the effects of ozone on human health is, according to the World Health Organisation's recommendations (*), the daily maximum 8-hour mean. Ozone effects should be assessed over a full year. Current evidence is insufficient to derive a level below which ozone has no effect on mortality.

However, for practical reason it is recommended to consider an exposure parameter which is the sum of excess of daily maximum 8-h means over the cut-off of 70 µg/m3 (35 ppb) calculated for all days in a year.

This exposure parameter has been indicated as SOMO35 (sum of means over 35), and is extensively used in the health impact assessments, including the Clean Air for Europe (CAFE) Programme leading to the Commission Communication on the Thematic Strategy on Air Pollution.

-Annoyance by noise (Eurostat, 2016)
Road traffic is, by far, the major source of traffic noise in Europe both inside and outside agglomerations. It should be also highlighted that significant numbers of people remain exposed to high levels of noise from rail and aircraft.

When available data allows for comparison between 2007 and 2012, different patterns have been observed: there has been a general increase of people exposed to all noise bands from airports, a slight increase of people exposed to noise from roads (only people exposed to lower noise bands), and a slight decrease of people exposed to noise from railways. Nevertheless, for 2012 reference year, information on strategic noise maps is missing for 12 out of 33 EEA member countries.

-Serious accidents at work (Eurostat, 2016)
Effective prevention requires that statistics are reliable and accurate enough to allow the identification of industries, occupation and work tasks where there is a high risk of accident or disease. The measures can then be focused on these tasks and future cases may thereby be prevented.

In the European Union, the Commission's Community strategy (2007–2012) on health and safety at work aims to improve the quality and productivity of working life. Health and safety at work is considered as one of the most important aspects of EU policy on employment and social affairs. The overall objective of the strategy is to reduce by 25% the total incidence rate of accidents at work per 100,000 workers in the EU-27 during the strategy period.

In the European Union, there is a legal obligation to report occupational accidents and diseases. However, there are practical differences on how the reporting systems have been established in different member states.

-Health status, health determinants and use of healthcare services; Healthcare; Healthcare: hospital discharges, hospital length of stay and medical procedures; Healthcare: human and physical resources; Healthcare expenditure (Eurostat, 2016)
Physical and mental problems, as well as ill health, undermine the quality and occasionally shorten the length of people's lives. They also inhibit economic and social development, by stripping countries of valuable human capital.

Poor health conditions mean that a significant part of a given population is unable to benefit from the general progress of society, or actively engage in civic activities.

Long and healthy lives are therefore not just an overarching personal aim for most people.

Moreover, since it has been shown that factors like people's lifestyles, culture and living environment affect health outcomes, objective indicators do not necessarily reflect the quality of healthcare services provided.

The state of people's health in Europe is therefore measured using a combination of objective health outcome indicators, such as life expectancy and infant mortality, subjective perceptions regarding access to healthcare and self-evaluations of health status.

The reason for using a combination of indicators is that healthiness in a given population is a complex matter and we need to look at it from various angles in order to present a more nuanced, complete picture of the reality.

These indicators include elements that constitute risk factors for health resulting from lifestyle, such as hazardous behaviours (e.g. smoking) likely to have an impact on future levels of health, and thus the well-being of European societies.

Satellite Health Accounts in Romania

An important feature of satellite accounts is that they keep, in principle, all basic concepts and classifications of the standard framework. Only if the specific purpose of satellite accounts requires an amendment changes are introduced in the basic concepts. In such cases, the satellite account should also include a table showing the links between the major aggregates of the account and the aggregates from the standard account. Thus, the standard framework holds its role as a framework of reference and at the same time there will be fulfilled several specific needs as mentioned by Costuleanu et al (2013).

Satellite accounts can respond to specific data requirements: they provide further details where necessary and eliminate unnecessary details; they extend the accounting framework by adding non-monetary information, for example information on pollution, environmental or health assets. Satellite accounts provide the opportunity to make links between such non monetary statistics and the standard framework of the national accounts. In this way, we reach to a consistent extended framework. This

framework can serve as a database for analyzing and evaluating all types of interactions between the variables in the standard framework and those of the extended framework as already underlined by Costuleanu et al (2012).

For Romania, the methodology for compiling statistics on Central and Local Government and social security operations is loosely consistent with the statistical framework set out in COFOG. From January 2006 the budgetary Classification was harmonized with the ESA 95 and with the GFS Manual 2001. Costuleanu and Georgescu (2011) showed that, in the functional classification of expenditures, the most significant are: general public services, defense, public order and safety, education, health, recreation, culture and religion, social protection, housing and community amenities, environmental protection, economic affairs (general economic, commercial and labor affairs, agriculture, forestry fishing and hunting, fuel and energy, mining, manufacturing and construction, transport and communication).

"The 2008-2010 multi-annual national statistics program", developed by the National Institute of Statistics (2011) provides in the chapter of the satellite accounts only: environmental satellite accounts, natural resource accounting and health satellite accounts. "The 2008-2010 multi-annual national statistics program" includes some actions on health satellite accounts for 2008 (implementation of data collection on health expenditure, harmonized with OECD methodology and with the most recent methodological recommendations of Eurostat), yearly (for the collection of health expenditure of the three areas: funding sources, health functions and services, health service providers; an additional field is the collection of expenditure on health human resources in the standardized format), for 2009 (review the national methodology of the System of Health Accounts, following the preparation and publication of the second edition of the OECD-EUROSTAT-WHO methodology) and for 2010 (dissemination of statistics on health expenditure).

Conclusions

When designing and compiling a satellite account, applying the concepts of the main framework for a specific purpose often results in the discovery of certain characteristics. This concept is also applicable in the case of health satellite accounts. Our results clearly demonstrated that, from the point of view of their aim, these characteristics may be helpful, but they can also present previously unforeseen limitations, especially in particular cases as Romania.

Abstract

Social media tools have made quick communication and free speech a reality, and yet many organizations still do not understand what social media tools are or how to deal with such phenomena. To help organizations deal with this new fast-spreading media a new breed of companies has come into existence; for example, 'socialeyez', 'meltwater', 'mccolins media', 'phenomena' and 'shareable brands'. These new companies provide services such as: media monitoring, listening analysis, newsletters, newsfeed and brand marketing etc. The main aim of this research is to answer the following question: Is it strategically better to use social media management tools or to hire a social media company to manage an organization's social media interaction? The objectives of this study are: 1) to explore the available social media tools that could be used to manage and utilize social media interaction; 2) to investigate the nature of the new breed of social media companies: how successful are they?; what tools do they use?; what kind of services do they provide?; 3) to find out how organizations are utilizing social media: do they have social media policies?; what tools do they use?; are they hiring social media companies to work for them?; if they are, then what are the benefits of employing such companies?) To achieve the research objectives, multi-method research was conducted, which comprised: 1) a literature review (journal, conference papers); 2) an examination of the social media companies' websites (and other online resources); 3) a short survey on the social media companies (sent by email); 4) a short survey on the private/public organizations (also sent by email).

Keywords: Social media tools and companies, government, monitoring, analysis, listening and management tools

1. Introduction

The adoption of social media in the public sector, as in the private sector, is considered to be a crucial step in the transformation of ways of governing, and in companies' communication and engagement with the public [Gharawi et al., 2010]. Recently, the strongest trend that has been observed globally is obviously the use of social media in both public and private sector organizations. It is used as a tool for both internal and external communication, for creating awareness, improving the delivery of services, building an image, protecting a company's reputation, shaping the way of thinking towards a company's products or services and interacting with citizens [Gharawi et al., 2010; Kasper et al., 2012]. Hence, many public and private sector organizations worldwide realize the power of social media in reaching out to their audiences and engaging them in both on and offline activities of the organization.

The appreciation of the value of using social media tools in government organizations and companies is increasing day by day. However, both public and private sector organizations have faced some challenges regarding management of these tools. These challenges occurred because: 1) there was no creative social media team who were able to manage social media tools effectively; 2) there was a lack of balance between openness, government organizations' or companies' strategy and their management process, and 3) there was no, or insufficient, monitoring of social media content [Macnamara and Zerfass, 2012]. In order to meet these challenges, organizations should answer the following questions: "what to do (strategy), how to do it (organization: roles and processes) and which tools would offer support in doing it (information systems)" [Kasper et al., 2012]. These questions can be answered by taking into account the vital process named 'social media management'.

Social media management is a process that leads to the accomplishment of organizational objectives by identifying and mitigating risks, listening, interacting, and reflecting on social media interaction from a stakeholder's perspective [Montalvo, 2011; Zhang and Vos, 2014].
This research will attempt to answer the following research questions:

- What is Social Media Management (SMM)?
- How do public and private sector organizations manage their social media interaction?
- Which is better for public and private sector organizations: using social media management tools to manage their social media presence and interactions or hiring a social media company to do it?

This paper is organized as follows: Firstly, the paper presents the methodology used in this research. After that, it presents a brief review of social media, with a particular focus on social media management (SMM). The findings are then discussed. The paper concludes with remarks and recommendations on which of the two methods is better and in which situations.

2. Research Methodology

To achieve the above objectives multi-method research was conducted which comprised: 1) a literature review (journal, conference papers); 2) an examination of the SM companies' websites (and online resources); 3) a short survey on the SM companies (sent by email); 4) a short survey on the private/public organizations (sent by email).

The gathered data was critically analyzed and synthesized in order to arrive at a complete understanding of which method is better for public and private sector organizations; using social media management tools or hiring a social media company to manage their social media interactions.

3. Literature Review

3.1. Social media for public and private sector organizations

Because of the extensively perceived benefits, the public sector (government agencies) are increasingly using social media to communicate and build relationships with employees and other stakeholders [Macnamara and Zerfass, 2012]. Shah and Lim [2011] confirm that social media tools play a vital role in connecting government with their citizens. Hence, a significant aim of adopting social media in the public sector is to raise government's interaction with citizens by sharing information and allowing them to participate in decision-making in order to achieve more transparency, engagement and participation [Mergel and Bretschneider, 2013].

Regarding social media usage in the private sector, it is not considered a luxury but simply as being required for reinforcing the reputation of companies, increasing stockholders interest and awareness, facilitating the exchange of information between firms and their consumers, enhancing interactions with brands and building new business relationships [Broekemier et al., 2015].

Once the public and private sector organizations have begun to adopt social media, a range of reactions occur. There are many organizational factors that might be influenced such as; organizational size, organizational management and structure, internal and external information, and stakeholders characterization [Broekemier et al., 2015; Mergel and Bretschneider, 2013]. It is important for both government agencies and companies who are on social media to take all these factors into consideration as they have importance not only for them but also for the public. If they do not deal with these factors appropriately and professionally, government agencies and companies will be affected adversely, impacting their image and reputation. Therefore, the proper way to overcome this dilemma lies in: 1) acting, representing the strategy and meeting the goals of organizations when using social media; 2) defining to what extent the government agencies and companies meet the criteria of using social media which are indicated by Veldhuis [2013]; knowledge, monitoring, sharing and relations, presence, strategies and policies and finance, and 3) managing government social media accounts by implementing social media management tools to enable interaction, growth, content posting, audi-

ence and engagement (e.g. number of followers, likes and views, comments and favorites, post activity, visits and reach) [King, 2015].

3.2. Social Media Management (SMM)

Due to the rapid growth of social media use around the world, it is expected that social media are significantly affecting operations, performance and an improvement in relationships of organizations in both the public and private sector [Chelliah and Field, 2014]. Online reviews, online interaction, e-participation and e-consultation are some of the benefits that social media tools offer these public and private sector organizations. Accordingly, organizations should make serious efforts to understand the influence of social media in order to prepare better management processes. This will enable and support the achievement of the organization's objectives, the analysis of social engagements and reactions, and evaluation of the outcomes of specific strategies [Montalvo, 2011].

Social media management is a process that helps organizations to manage outbound and incoming online interactions in a more efficient manner by helping organizations to more easily monitor what people are saying about their services and products and helping to increase their social media presence across several social networking sites [McCabe, 2010].The most important purposes of using a social media management process are indicated by Kasper et al. [2012]:

- Reputation management
- Improving product and building brand image
- Risk management
- Interaction and dialogue management
- Content and activities listening and analyzing.

Arguably, social media management comprises three main processes: *monitoring*, *listening* and *analyzing*. These processes can be achieved by using several tools which offer many features to manage the social media accounts of organizations. Each of these processes is outlined below:

3.2.1 Social Media Monitoring

Social media monitoring has become an essential process of tracking and scanning the organization’s situation and evaluating its operations [Zhang and Vos, 2014; Macnamara and Zerfass, 2012]. Basically, it is used for observing and evaluating interactions through listening to conversations, identifying the issues that are being discussed, opinions, and the positive or negative comments about the organization that are posted online. The most important considerations of social media monitoring are to find out what others think about their products, brands and services and those of their competitors [Laine and Frühwirth, 2010; Macnamara and Zerfass, 2012], and to follow the development of a particular phenomenon that has been identified in the social media dialogue [Zhang and Vos, 2014]. To sum up, the monitoring of social media can be defined as listening, finding out and interpreting what people are saying online about an organization [Stavrakantonakis et al., 2012].

3.2.2 Social Media Analysis

Social media analysis is the practice of gathering data from social media websites and analyzing them to identify users’ sentiments and identify the trends to follow in order to better meet their needs and wants. Social media analysis entails measuring, analyzing and interpreting interactions and relationships between people, topics and ideas [Ambler, 2011]. Furthermore, Montalvo [2011] indicates that “Social media data analysis entails translating data into dashboards, graphics, and metrics reports, which management uses to evaluate the outcomes of specific strategies".

In order to make an effective analysis of social media content, most of social media channels offer some type of analysis or insight that can help an organization to monitor its performance and user's trends and to gather social media information [Lawrence et al., 2010]. Some of these tools are; Google Analytics, Facebook Insights, Twitter Analytics and LinkedIn Analytics.

3.2.3 Social Media Listening

The ability to make an appropriate decision for such an organization and create solid relationships between citizens and the organization through social media content depends on how the comment and online posts are measured [Schweidel and Moe, 2014]. The measurement of the interactions and conversation in social media is called 'social media listening'. This process helps an organization to find out what people are saying about its services and products and then responding appropriately through sorting out their sentiments, comments and posts by their tone or sentience (negative or positive), style (serious, funky, professional), demographics (age, gender, location) and the influencers with the organization's products or services [Schweidel and Moe, 2014]. Correct listening to the social media interaction will improve trust between users and ensure that they stay connected and engaged [Crawford, 2009]. Added to that, social media listening can benefit the organization in the following ways: 1) provide solutions to problems by listening to the users' expectations; 2) identify 'influencers' and 'advocates'.

To sum up, the social media management process offers a means of listening to the social media users and analyzing and measuring the organization's activity in relation to a brand or enterprise, a process that can lead to valuable insights for enterprises regarding which strategy they should employ, how customers view their services and solutions, what the enterprise should expect in the future or which of their offered features are not as effective as had been estimated [Stavrakantonakis et al., 2012].

3.3. Social Media Tools vs. Social Media Companies for Managing Social Media

Managing social media interactions is undertaken by using several tools that are widely used worldwide, which can be obtained commercially or for free. The selection of these tools depends on certain criteria that an organization should take into consideration, such as: cost, supported language, various sources that are aggregated, geographical, historical and sentimental analyses. These tools have been established to support multiple functionalities, such as "analyses of volume, source, author, keyword, region, sentiment, and then reporting these analyses conveniently and in a graphical fashion" (Laine & Frühwirth, 2010, p. 195). However, some of these tools are limited in terms of functionality. This note is more applicable when using free tools that provide one functionality or insight into one media type [Laine and Frühwirth, 2010]. Table 1 shows some of the available social media management tools.

Table 1: Shows some of the available social media management tools

On the other hand, there are many companies working in the social media field worldwide and in GCC countries specifically. They offer several services related to managing social media accounts; analyzing, monitoring, listening and developing social media strategy. Table 2, below, highlights some of GCC social media companies together with the services they provide.

Table 2: Some of GCC social media companies together with provided services

No	Company's name, location and URL	Services
1	Alamah (Oman) http://www.alamah.om/	• Development of strategy. • Managing accounts and preparation of periodic reports. • Helping companies to develop their websites. • Help to make programmed systems that are fast, friendly, and safety. • Developing phone applications that are easy to navigate.

2	Galaxy way (Oman) http://www.galaxy-way.net/home.html	• Creating an identity for the brand. • Creating social media campaigns for the promotion of the brand. • Online promotion. • Advertising for companies in TV and Radio. • Managing events for companies. • Designing brochures and adverts for companies. • Providing companies with posters and signage.
3	Bayantebyan (Oman) http://bayantebyan.com/	• Building public relations between companies and clients. • Online listening. • Managing events and corporate social responsibility. • Offering creative and productive workshops for clients.
4	Wassm Media (Oman) https://instagram.com/wassmmedia/	• Offers a variety services in the field of social media
5	Proshots (Oman) http://www.proshots.org/	• Providing services for Creative Marketing Solutions, Photography, Videography, Film-making, Media Coverage, Event Management and Coverage, Projects Management, Digital Production, 3D Animation, Graphic Design and Sound Production.
6	Socialeyez (UAE) http://social-eyez.com	• Monitoring and analysis of social media for any organization to get a complete picture of public opinion and the relevant trends. • Creating a strategy plan for branding. • Developing mobile application.
7	Meltwater (UAE) http://www.meltwater.com/ae/	• Monitoring the news on the internet and social media. • Managing the interaction between clients and social media. • Analyzing the performance of social media.
8	McCollins media (UAE) http://mccollinsmedia.com/	• Managing and improving the public relations with clients. • Listening to what others say about the brand. • Designing mobile application. • Helping clients to develop their website. • Producing a short video for advertising.
9	Phenomena (UAE/ Dubai) http://www.phenomena.me/social/	• Managing the communication with others via social media. • Advertising brands on social media. • Developing Facebook applications. • Making videos to proliferate brand awareness on social media. • Helping clients to develop their websites.
10	Shareable Brands (UAE/ Dubai) http://www.shareablebrands.com/	• Creating a successful strategy for marketing brands. • Doing research to develop a strategy for brands. • Developing communities by sharing the right content with the right people. • Monitoring and evaluating what others say about companies. • Helping to select the right tools to manage customer interactions and develop processes.

11	Popalmedia (UAE/ Dubai) http://popalmedia.com/	• Animated explanatory video.
12	Zynosure (UAE/ Dubai) http://www.zynosure.com/	• A creative agency for maintaining the consistency of brands. • Offering high impact videos and animations. • Helping companies to design and develop their websites. • Creating advertising for companies in both traditional and digital fashions. • Design and development of E-books. • Online marketing services that offer web marketing, email marketing and social media marketing
13	Global Media Insight (UAE / Dubai) http://www.globalmediainsight.com/	• Maintenance of websites. • Developing mobile applications. • Creating attractive presentations for companies. • Creating advertising for companies in both traditional and digital form. • Listening to what others are saying about the brand, analyzing it and then communicating with others in a positive way.
14	Alsayeghmedia (UAE) https://www.alsayeghmedia.com/	• Helping the client to plan research and create strategies for their companies. • Providing social media management which allows an individual or an agency to manage online interactions in an effective manner. • Making corporate videos, event videos and documentaries for clients. • Managing public relations for clients. • Helping to manage big events. • Helping clients to market their brand online. • Providing a media-buying agency. • Producing audio for clients.
15	Buz (UAE) http://www.ibuz.ae/	• Providing a consultancy service in management and marketing for clients. • Helping clients to organize strategic events and trade exhibitions. • Managing public relations in order to build company brands. • Teaching company managers how to choose staff for positions in the company.
16	Arabia Company For Digital Publishing and New Media (UAE) http://www.arabioo.com/	• Designing and managing digital advertisements. • Producing short videos for advertisements.
17	iclick (Saudi Arabia) http://iclick-sa.com/	• Providing training and workshops for clients in digital marketing, social media marketing and mobile marketing. • Improving the marketing of mobile applications. • Providing a consultancy service in marketing for clients. • Improving digital marketing and online advertising. • Improving social media marketing. • Using Google analytics to build an analytics plan for clients.

18	Social media solution (Qatar) http://socialm.qa/	• Offering a consultancy service in marketing. • Giving training in marketing. • Creating strategies in marketing and operations. • Content management. • Monitoring and analysis of social media accounts.

In order to manage social media interactions successfully and effectively, organizations should consider which way would be the most appropriate by identifying the pros and cons of each. In fact, there are two ways of tackling social media management: either by using the social media tools and forming a local team within the organization or by hiring a third party company to manage the presence of an organization on social media. In the next sections both ways will be discussed in more detail.

- *Using Social Media Management Tools and Forming a Local Team*

This way of managing organizations' social media interactions depends on the social media representative person/team using the tools that are available, whether free or commercial. The advantages for organizations in doing it this way are as follows: 1) it is easy to identify the target audience; 2) it is easy to find solutions and to connect with other departments in the organization; 3) followers' questions can be answered quickly; 3) it can provide a better understanding of the organization's concepts, and 4) the human side of the organization can be presented more easily. Therefore, it is recommended to start up a social media department (team) that has the same characteristics and features as have the other departments. This is necessary because of the significance of social media in this era, it having increased in a way similar to the evolution of the marketing department, from an era when there was no IT to the present day. This social media department (team) would be responsible for managing all organization accounts in social media.

On the other hand, there are some challenges in adopting a local team for managing social media, especially if the team members do not have the experience and skills to manage, interact, engage and monitor.

- *Third Party Company to Manage Social Media Presence/Interactions*

In terms of hiring a third party company to manage the social media presence and interactions, the organization can achieve an acceptable level of quality in order to meet the strategic goals, as follows: 1) by presenting quality and professional social media content (i.e. picture, video, ads, and infographic) that promote branding image and message; 2) by managing accounts more efficiently with skilled and experienced team members, and 3) by creating a comprehensive strategy that reflects the goals of the organization [Zailskaite-Jakste and Kuvykaite, 2012]. To achieve the desired quality social media companies should make serious efforts to understand the impact on the organization of online interactions and prepare better strategies to manage social media presence effectively [Kim et al., 2015].

However, organizations who decide to hire a third party company to manage their social media presence and interactions might face some challenges such as: 1) high costs, including the strategy-building cost, design cost, media coverage cost for events and activities, and proofreading cost; 2) lack of knowledge about the organization and its objectives and strategies; 3) delay in responding to audience inquiries because they need time to contact someone from the organization itself; 4) inability to show the positive side of the organization while interacting with the audience, and 5) inability to measure the impact of social media content. The diagram below summarizes the concept of social media governance.

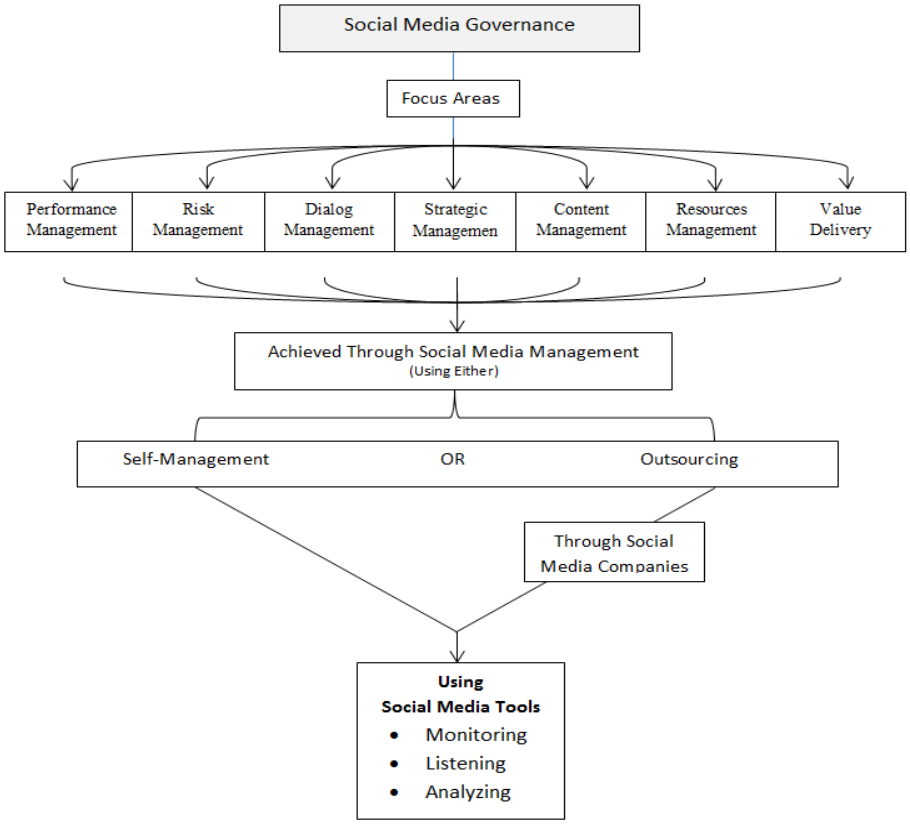

Fig. 1. Social Media Governance

4. Findings & Discussion

The managing of social media presence, interaction and content for any organization plays a vital role in ensuring that it meets its goals and needs, builds its brand, protects its reputation and manages the interaction. The ways of managing social media presence, interaction and content that are outlined in the previous section differ from one organization to another, depending on the following factors: budget, employee's skills, how complicated its operations are, its structure, and available services or products. The following review is an attempt to answer the research question: "Which is better for public and private sector organizations; to use social media management tools and form a local social media team or to hire a specialized social media company to manage the social media presence and interactions?"

Why should organizations build their own social media team?

In order to avoid the high cost of hiring a specialized social media company, organizations should build their own social media team that has the interest, knowledge and skills to work as a creative social media team. Thus, this team should have good integration skills and competence in the following areas: digital content, public relations, design, quality assurance, photography, marketing, branding, developing strategy, content analysis, and using information technology.

Cost is not the only reason to avoid hiring a specialized media company to manage an organization's social media presence. It is well known that organizations are keen to present content that is valuable, of quality, and that has been carefully selected. Therefore, responding and interacting with their audiences will be quicker and more efficient because no one can answer audience enquiries better than the local social media team (within organization) and the team can easily connect/interact with other

departments within organization at the same time. The structure of the social media department/team could be cross-functional, which enable easy and fast collaboration, and hence, response.

In case the local social media team lacks the required skills and capabilities, the organizations can resolve this challenge by seeking training and consultancy from the specialized social media company "*to plan the social media implementation process, to set up the purpose, to plan resources, to define the target audiences, to select social media channels and to pursue planned actions*" [Zailskaite-Jakste and Kuvykaite, 2012] .

5. Conclusion

This paper investigated how to manage social media presence and interactions in public and private sector organizations. It was found that there are three main processes involved in the management of social media presence. They are:

- Monitoring: observing and evaluating online interactions.
- Listening: paying attention to the online interactions.
- Analyzing: analyzing the online content in order to turn it into valuable insights [Stavrakantonakis et al., 2012].

In order to monitor, listen and analyze social media presence and interactions, there are several tools that are available, which play a significant role in social media management.

In comparing the use of social media management tools by forming a local team within the organization and hiring a third party company to manage the social media presence and interactions of the organization, it was found that which one is the best option depends on a number of factors, such as: its organizational philosophy, culture and vision, budget, structure and how complicated its operations are, its size, services or products, and its employee's skills. Therefore, these factors should be considered when deciding to do it yourself or to hire a third party company to do it for you.

Abstract

The paper aims to contribute at the debate on smart tourism destinations as intelligent configuration of regional integrated and multi-sectorial system, evaluating the promptness of Apulia, as regional destination of growing popularity. At this purpose, a web-survey was used to gather data regarding the level of use of technologies, internet and social media for communication; the collaboration attitude and the level of integration with the other actors of the tourism system for creating new and innovative business opportunities; the level of interaction and collaboration with customers for experience and service co-creation; and the advantages and the main drawbacks related to the use of ICT applications. The results of context analysis evidence that the Apulian offering of hospitality need to invest more in the ICTs' infrastructure, increasing digital services for customers and employees as well as in the creation of a cultural background able to sustain the process of emancipation of the destination in a smart perspective. Moreover, results suggest also the needs to create a culture of collaboration, enhancing dynamic interaction between diverse tourism actors.

Keywords: smart tourism destination, tourism network, social network diffusion, service co-creation.

1. Literature Background

1.1. Smart Tourism Destination

There is growing evidence that in the current economic order the innovation and competitiveness is increasingly driven by open-collaboration networks where systemic innovations are the results of strategic pooling of knowledge, resources, interactions, facilities, competences exchanges, and collaborations and competitive positions of a diversified set of interrelated stakeholders. Innovation activities are increasingly taking place through collaborative networks that are open, cross-border by nature and are governed by open business models (Chesbrough, 2006).

Within this context, there is a need for smart innovation instruments that reflect the networked and systemic character of innovations and can act as catalyser's of systemic change (Albino et al., 2015).
In this logic, the smart cities concept has emerged recently conceptualized 'as territories with high capacity for learning and innovation, which is built-in the creativity of their population, their institutions of knowledge creation, and their digital infrastructure for communication and knowledge management' (Komninos et. al, 2011).

The smart city projects provide an integrated view of the cities and underline that in a dense environment like that of cities, no system operates in isolation.
The smart city concept has been developed, experimented, and demonstrated during the last years within a series of Europe-wide projects as well as in national initiatives.

In order to improve quality of life and services efficiency through an optimal use of Smart City literature, tourism is considered a goal for a Smart City, which embraces tourist activities that are performed and supported by smart technology (Gretzel, et al., 2015a). Therefore, the concept of Smart Tourism Destinations emerged from the development of Smart Cities, where technology is embedded within the city resources (Vicini et. al, 2012).

A tourism destination can be compared with a cluster of interrelated stakeholders embedded in a social network that interact, jointly meeting visitor needs and producing the tourism experience (Baggio et al., 2010). Considering the information-intensity of tourism and the technology relevance for tourism, contributing to alter the way travel is planned (Neuhofer et al, 2014), business is conducted (Ndou, 2011) and tourism services and experiences are created and consumed (Del Vecchio et al., 2015; Stamboulis and Skayannis, 2003), the smartness concept could be increasingly applied to this sector.

The Smart Tourism Destination is understood as a local tourism system characterized by advanced services, high degree of innovation and the presence of open, integrated and shared processes for enhancing the quality of life for both residents and tourists (Florida, 2003; Komninos, 2002, Shapiro, 2006; Hollands, 2008; Caragliu et al., 2009, Micera et. al 2013, Wang et al. 2013).

Principally, the focus in Europe, has been more on innovation and competitiveness and developing smart end-user applications that support enriched tourism experiences using already existing data combined and processed in new ways (Lamsfus et al. 2015; Boes et al. 2015a, b).

This relation of smart tourism destination with smart technologies is mainly due to the tremendous growth of the diffusion of search engines, new distribution channels, virtual tourism communities and numerous social media platforms that have emerged recently support tourists to make smart decisions (Buhalis and Law, 2008; Law, et al., 2014; Sigala, Christou and Gretzel, 2012; Xiang, Wang et al., 2015).

The diffusion of mobile technology (smart-phone) has further transformed the tourism experience enhancing the tourists empowerment by bringing together information search, communication, entertainment, social networking and mobility-related functionalities (Tussyadiah and Zach, 2012; Wang and Xiang, 2012). Moreover, tourists are shifting the competition toward the co-creation experience as a basis of value and as the future of innovation (Prahalad and Ramaswamy 2004, Binkhorst 2006).

However a smart tourism destination in not based simply in technologies and the new approaches to data collection, management and sharing. Instead it encompasses technology, people and institutions (Nam and Pardo, 2011). According to Nam and Pardo (2011) the smartness is increasingly related to human capital (their creativity, diversity and education) and social capital, which facilitated and supported by ICT infrastructures fuel sustainable growth and enhance the quality of life. Therefore the creation of a smart tourism destinations requires the integration of technologies, systems, services, and capabilities into an organic network that is sufficiently multi-sectorial and flexible for future developments, and moreover, open-access (Albino, et al., 2015).

Recently diverse academics and researches have embraced this conceptualisation of smart tourism destination. According to Buhalis and Amaranggana (2015; 2014), a Smart Tourism Destination is the result of the interconnection of tourism destination with multiple stakeholders communities through dynamic platforms and knowledge intensive flows of communication and enhanced decision support systems. The final objective is to enhance tourism experience through an effective resource management maximising both destination competitiveness and consumer satisfaction while also demonstrate sustainability over an extended timeframe.
Lopez de Avila (2015) defines the smart tourism destination as an innovative tourist destination, built on an infrastructure of state-of-the-art technology guaranteeing the sustainable development of tourist areas, accessible to everyone, which facilitates the visitor's interaction with and integration into his or her surroundings, increases the quality of the experience at the destination, and improves residents' quality of life.

It is worth to note that in Smart Tourism Destination, the available technology is used in order to enable the co-creation value and experiences for tourists and wealth, profit, and benefits for the organisations and the destinations (Boes et al., 2015). In fact, different authors, consider smart experience as an output of smart tourism that derives from a social phenomenon arising from the convergence of ICTs with the tourism experience, and its enhancement through personalization, context-awareness and real-time monitoring (Hunter et al. 2015; Buhalis and Amaranggana 2015).

From a managerial perspective, a smart destination enables DMOs, institutions and tourism companies to make their decisions and take actions based upon the data produced in within the destination, gathered, managed and processed by the ICT infrastructure (Lamsfus et al., 2015).

1.2. The features of a smart tourism destination

Following the literature review, on the state-of-the-art of knowledge on smart tourism destination some significant key dimensions and features for characterizing it emerges. In Table 1 are highlighted the main features found in literature.

Table 1: Features of Smart Destinations in literature

Features	**Authors**
Interconnection Cluster of interrelated stakeholders; interconnection of tourism destination with multiple stakeholders communities	Nam and Pardo (2011) Baggio et al., 2010 Buhalis and Amaranggana (2015; 2014)
Technology is embedded ICT is a driver Dynamic platforms Smart technology High-tech communication facilities	Vicini et. al, 2012 Gretzel, Sigala, Xiang & Koo, 2015a) Lopez de Avila(2015)
Advanced services Innovation and integration Skilled labor force Intense and open network linkages Creative business activities High degree of innovation Iintegrated and shared processes	Florida, 2003; Komninos, 2002, Shapiro, 2006; Hollands, 2008; Caraglio et al., 2009, Micera et. al 2013, Wang et al. 2013 Buhalis and Amaranggana (2015) Nam and Pardo (2011)
Tourists empowerment mobility-related functionalities smart experience at the destination	Tussyadiah & Zach, 2012; Wang & Xiang, 2012 Lopez de Avila(2015)
Knowledge intensive flows of communication enhanced decision support systems	Buhalis and Amaranggana (2015; 2014)

In the smart tourism destination ICT infrastructure is considered an enabler, a facilitator for creating a new type of communicative setting. In a tourism setting, technology is the key component that promises to supply tourism consumers and service providers with more relevant information, better decision support, greater mobility, and ultimately, more enjoyable tourism experiences (Gretzel 2011; Werthner 2003; Sigala and Chalkiti 2014).

However the ICT cannot automatically create smartness (Shapiro, 2006, Hollands, 2008), instead creative skills, innovation-oriented institutions, open innovation, and user engagement, broadband networks, and virtual collaborative spaces (Komninos, 2011) are other relevant dimensions of a smart tourism destination.
The smartness of tourism destination is based upon the dynamic interconnection among different stakeholders for service co-creation, service exchange and value co-creation (Gretzel et al 2015). Social media and internet tools are instrumental in enabling firms to develop such dynamic connections, as technologies enable them to network.

Following these dimensions and features it emerges as the creation of smart tourism destinations requires the existence of some conditions related to human capital, social capital as well as a rich environment of broadband networks to support intelligent applications.

Departing from these insights, the aim of this paper is to make an evaluation of the state of the art conditions in the Apulia destination to analysis its promptness as well as for proposing an effective approach for promoting the creation of a smart tourism destination in the location.

Following the literature review and the emergent features of a smart tourism destination, the paper aims to evaluate the following items:

- level of use of technologies, internet and social media;
- collaboration attitude and the level of integration with the other actors of the tourism system for creating new innovative opportunities;
- the level of interaction and collaboration with customers for experience and service co-creation;
- the advantages and the main limits related to the use of ICT applications.

2. Research Methodology

A survey methodology was used in this study to gather data regarding the promptness of the location to adopt a smart destination approach. The target population consists on tourism firms operating in the Apulia Region. The sample of tourism firms operating in the Apulia Region were obtained firstly by the official Apulian Destination Management System www.viaggiareinpuglia.it and then it was integrated with other information source such as the www.bed-and-breackfast.it, web searches and secondary source. In total the sample obtained was composed of 500 Tourism accommodation firms (hotels and bed and breakfast, etc.). The questionnaires were administered online through Google Drive. The rate of return obtained was 23%, with 130 questionnaires filled in. The survey was administered on the time period September-November 2014.

The questionnaire was formed by two main parts. The first part dealt with the profile and characteristics of the tourism accommodation firms in terms of typology of business, number of rooms, services offered to tourists, number of presences and nationalities of tourists. The second part consisted of the items aimed to measure the level of promptness of the destination to make the leap toward the smartness.

In specific questions aimed to measure the level of use of technologies, internet and social media; the collaboration attitude and the level of integration with the other actors of the tourism system for creating new innovative opportunities; the level of interaction and collaboration with customers for experience and service co-creation and finally the advantages and the main limits related to the use of ICT applications were designed and addressed to the sample population.

3. Findings

Table 2 synthetizes the data related to the level of use of technologies, internet and social media by the companies participating to the survey. In particular, the study focused on analyzing the typology of technological tools and solutions used as well as their main functionalities such as booking, reservation, customer satisfaction monitoring, etc..

Table 2: Level of use of technologies, internet and social media

Use of technologies (Nr)						
Internet Technologies	Systems for users profiling	Virtual guides, interactive maps, 3D rebuilding, augmented realities	Digital Marketplaces (booking.com, expedia.com, ecc.)	Mobile Applications	CRM Systems	Social networks (twitter, Facebook, etc) Blogs, and forums
128	69	54	86	23	2	111

Typologies (Nr)										
Adv. on Internet	Company web site	Newsletter	RSS	Podcast	Instagram	Video Sharing	Facebook	Chat	Twitter	Blog	Pinterest
115	117	44	20	14	23	34	111	29	36	28	19

Channels used for booking and reservations (Nr)								
Telephone	e-mail	Booking online on corporate web site	Facebook (with the usage of the specific app)	Twitter	Apps for mobile devices	Online booking websites	Online promotional web sites	Other online tools
112	127	67	19	1	16	78	9	6

Tools to monitoring customers satisfaction (Nr)									
Questionnaires	E-mail	Feedbacks/ Reviews	Forum	Blogs	CRM systems	Software for statistical analysis	Social networks	Traditional tools (guest book, etc.)	Vis-à-vis
43	43	114	3	7	2	2	53	41	10

Reasons and Areas of Usage of Internet (1-7) (Media)										
Managing requests of info from customers	Managing booking online and reservations	Managing booking and reservation telematics tools	Managing promotions and special offerings	Managing customers and fidelity initiatives	Market researches	Buying of products and services	Communicate with public administration	Managing relationships with industry and association of categories	Monitoring and management of online feedbacks	Online payment (credit cards, paypal, etc).
6,55	6,72	5,55	5,85	5.65	4.34	4,02	4.41	4.34	6,19	4,30

As it could be evinced by the table generally the sample expresses a positive feedback related to the use of internet technologies (128/130). Furthermore, 69 companies adopt systems for users' profiling; 54 adopt virtual guides, interactive maps, 3D rebuilding and augmented realities; 86 responded to active on digital marketplace and booking online platforms; 23 have developed a mobile application; while just 2 businesses reported to use a CRM system.

In relation to the use of social media networks, the results are highly positive and optimistic, as 111 companies out 130 have an official profile on at least one of the most popular ones.

In terms of typologies of ICTs used, a large number of companies (115 on 130) use online advertisement services (Adwork and similar), 117 of them have a web site and 44 the companies using newsletter. As for the presence on the social networks and web 2.0 technologies, Facebook is the most used one (111 on 130), followed by Twitter (36 on 130), video sharing platforms (34 on 130), chat (29 on 130), blogs (28 on 130) and Instagram (23 on 130). Less used are RSS technologies, Pinterest and Podcast.

Focusing on the comprehension of trends related to technologies adopted for booking and reservations it is possible to note that email is the technology mostly used (127 on 130), followed by the telephone that remains an useful tool for 112 companies. Online booking systems are used by 87 companies by demonstrating to be adopted for acquiring reservation more than booking online corporate web sites (67 on 130). Although the commercialization by online travel agencies and marketplaces limit the margin of profit for companies, those tools are more used than own services. This demonstrate that there is a lack of confidence by the companies into their commercial capability. At this purpose it could be more useful to take part in or be present on smaller platforms (i.e. www.bed-and-breakfast.it) or in association of categories that by allowing to reach a larger audience could assure lower fees. It is low the rate of usage of social network as well as of mobile apps.

In relation to the monitoring of customers satisfaction, the preferences expressed by the sample can be easily clustered around the feedbacks and reviews (114 on 130), social networks (53 on 130) and questionnaires (43 on 130). The evidences collected demonstrate a wide process of digitalization (with the only exception of questionnaires, all the other tools adopted are digitally supported). However, it is missed the usage of advanced systems of monitoring, such as business intelligence, that is adopted only by 1 company.

The reasons and areas of usage of the Internet have been evaluated on a scale from 1 to 7, where 1 means never and 7 always. With an average of 6.72, the web is used for managing online reservation, to work and satisfy requests, with an average 6.55, to monitor feedbacks from customers, with an average of 6.19. The usage of the Internet for promotional campaigns, customers' retention strategy and updating of databases for newsletters and online transaction is, instead, low considered. At this purpose it is reasonable to derive a relevant gap from the smaller companies and the larger ones, considering that if the presence on OLTAs (parity rate) of those last ones requires the usage of the Internet the smaller ones present a relevant lack of digital skills. Always low is the usage of the web for communicating with public administration (even if for the companies of capitals is mandatory), for market researches, for managing networks of relationships and online purchasing.

About the item 2, related to the collaboration attitude and the level of integration with the other actors of the tourism system for creating new innovative opportunities, the survey highlights a critical situation characterized by a weak attitude to collaborate (Table 3).

Table 3: Collaboration attitude and level of integration

Type of Stakeholder	Activities											
	Promotion/ Exploitation of the regional tourist offer	Training Activities	Participation at public or private call for funding	Joint services of consulting	Creation of an integrated tourist system	Co-working activities	Co-marketing and co-branding activities	Creation of new tourist product/services	Creation of regional brand	Activities of sensitization to adopt ICTs	TOTAL	TOTAL %
Consortia and Associations of categories	11	16	12	15	10	12	9	9	9	8	111	26,37%
Public Agency for management of tourist destinations	21	6	6	6	14	6	7	11	10	6	93	22,09%
Public Institutions	7	16	13	3	11	2	0	3	7	3	65	15,44%
Tour Operators	2	3	1	0	4	7	4	5	3	2	31	7,36%
Web Agencies (booking.com, expedia.com, ecc)	49	5	2	3	3	8	10	8	3	6	97	23,04%
Transport companies	0	0	0	0	4	2	1	2	0	1	10	2,38%
Organizations for the management of cultural heritage (es. Museum, etc)	0	0	0	0	0	0	0	0	0	0	0	0,00%
Universities and Training Centers	0	2	0	0	0	0	0	0	0	0	2	0,48%
Financial institution	0	0	1	2	0	0	0	0	0	0	3	0,71%
Agro-food companies	0	0	0	0	0	0	0	0	0	0	0	0,00%
Customers	4	2	1	1	0	0	0	1	0	0	9	2,14%
TOTAL	94	50	36	30	46	37	31	39	32	26	421	100,00%
TOTAL in %	22,33%	11,88%	8,55%	7,13%	10,93%	8,79%	7,36%	9,26%	7,60%	6,18%		

In general, the main reasons behind the launching of partnership is represented by the opportunity of grasping joint promotions and exploiting tourist offering based on the integration of a wide large community of actors (23%). Specifically, the collaborations are mainly with Online Travel Agencies (booking.com, expedia.com, etc.), followed by associations for the promotion and protection of area, public-private consortia or no profit associations. The updating of professional competencies has been identified as the second most important reason behind collaborations; the main actors interested in this case are consortia or associations and public institutions (32%), while there is a low level of collaboration with universities and training centers (0,48%), probably not perceived as close to the needs of professional figures and competencies required. About the creation of an integrated tourist

system, as further emerging reason of collaboration, the findings show a low propensity of firms to stretch partnerships (11%), as well as it is low the interest expressed by participants to the survey for the promotion/ enhancement of tourism vocation of the area (23%). In both the cases, Consortia or Associations are identified as the most practiced partners, followed by Online Travel Agencies (booking.com, expedia.com, etc.). Collaborations with universities and financial institutions are generally few and poorly diffused are also the forms of collaboration with customers, transport companies, car rental and tour operators. Completely absent are forms of structured collaborations with the agro-food and cultural players, by demonstrating a traditional and not integrated view of the industry.

Aimed to evaluate the level of interaction and collaboration with customers for experience and service co-creation, evidences on item 3 are synthetized in the following table.

Table 4: Level of interaction and collaboration with customers

	Score							
Customers Involvement	1	2	3	4	5	6	7	**Average**
… in the activities of Marketing & Sales	43	17	24	12	11	11	12	3,09
	33,08%	13,08%	18,46%	9,23%	8,46%	8,46%	9,23%	
… in the activities of Customers Care	53	14	17	12	12	10	12	2,32
	40,77%	10,77%	13,08%	9,23%	9,23%	7,69%	9,23%	
… in the activities of New Product Development	45	9	18	17	15	14	12	2,65
	34,62%	6,92%	13,85%	13,08%	11,54%	10,77%	9,23%	
as "part-time employees"	87	16	11	6	3	6	1	1,75
	66,92%	12,31%	8,46%	4,62%	2,31%	4,62%	0,77%	

On a scale from 1 to 7, where 1 means "not at all important" and 7 "all important", the attention reserved by companies interviewed to the strategy of value co-creation with customers demonstrates as the primary area of integration is the one related to marketing and sales activities (with an average of 3.09 on 7). Secondly, customers are identified as suitable partners into the activities of new product development with an average of 2.65. Although the score is lower than the average, the answers at this question present a meaningful distance in terms of feedbacks absolutely negative and absolutely positive ones, demonstrating that even if there a lack of awareness on the importance of collaborate with customers to innovate the offering of products and services, where it is present this is successfully exploited. On the same direction is also the question related to the customers' involvement to create contents and benefits for other customers (average 2.32). It is clearly few perceived the opportunity of considering customers as "part-time employees", by highlighting the need of investing in innovative entrepreneurial (average 1.75).

About the awareness on the opportunity of improvement of firms' competitiveness coming from the adoption of mobile application and the areas of main intervention, as argued in the item 4 of our study, the evidences collected are resumed in table 5.

Table 5. Opportunity of improvement coming from mobile application

Degree of improvement of competitiveness of the hospitality services based on the usage of a mobile application											
	No		I don't know		Yes, low		Yes		Yes, a lot		
Freq.	26		34		8		10		52		
Areas of improvement of competitiveness of the hospitality services based on the usage of a mobile application											
	Pre-experience	Local heritage knowledge	Communication	Visibility	Accessibility	Incentive	Overall Image	Virtual Guide	Instantaneous Info	Creation of unconventional paths/packages	Localization of beauties
Freq.	2	3	4	11	3	1	1	1	1	1	1

Although it is low diffused, companies interviewed expressed a large interested in experimenting the adoption of an application to sustain the firms' competitiveness. Even if with different level of awareness, 70 companies out of 130 have express a positive feedback about. As for the areas of intervention, there is a larger convergence on the benefits in terms of visibility and support to

marketing activities, followed by the improvement of the communication effectiveness and better usability of the areas and deepen knowledge of the destination in its larger definition.

Table 6. Advantage of social network adoption

Advantages of social networks adoption					
	Increase Total Customers	Increase Visibility	Allow Multi-channel Booking	Provide Multi-channel Support	Cost Reduction
No	53	18	66	71	77
Yes	77	112	64	59	53

About the opportunities and advantages associated to adoption of the social networks, there is a large expectation in terms of contribution at the company visibility (112 out of 130), followed by the increase of the customers (77 out of 130), reinforcement of the multichannel booking strategy (64 out of 130). While, the benefits of the adoption of social networks in terms of multichannel support and customers' service as well the opportunities of costs' reduction, are in average less perceived.

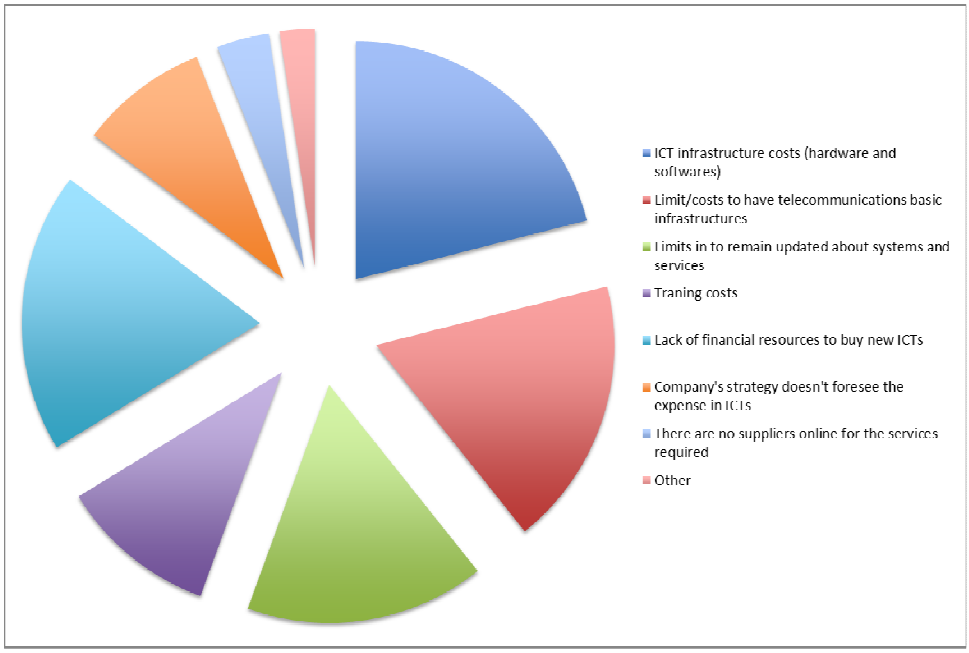

Figure 1. Limitations of ITCs adoption

Focusing on the limitations at the processes of digitalization and adoption of ICTs and web services, costs are identified as the most impacting on this process. There is a large convergence on the costs required both in terms of acquisition and maintenance of the technological infrastructure and training of human resources. This negative perception is surely influenced by the small dimensions of companies participating to the survey (in most of the cases, the stable working organization is based only on the entrepreneur) as well as by the lack of culture in terms of digitalization benefits registered also in the previous questions. This last point is also confirmed by the feature emerging in terms of attempt the process of updating required by the technological infrastructure. In addition to the limited monetary availability to support the investment required it is interesting to note as the weakness of the external infrastructure (broadband, wireless, etc) is a further negative factor affecting the attitude to invest in more developed ICTs or the effectiveness of the investment realized. In all the cases, the limits and disadvantages identified recalled the importance of a larger commitment of the public actors or destination managers in sensitizing, design and accompanying the process of infrastructural development and digitalization required by a smart destination.

Conclusions

Aimed to contribute at the debate on the creation of smart destinations as intelligent configuration of a regional integrated and multi-sectorial system resulting from the integration of technologies, systems, services and capabilities, the study has focused on the evaluation of the promptness of Apulia, as regional destination of growing popularity. The analysis based on a survey addressed to a sample of 500 tourism accommodation firms, with a rate of return of 23%, allows to delineate the profile of a tourist offering characterized by an usage of ICTs, still limited to assure a basic visibility of the firms on the web, as well as by a low awareness on the potentialities that an integrated and multi-channels strategy of digitalization can provide to the companies' competitiveness. The Apulian tourism supply (in specific hospitality sector) needs to invest in the reinforcement of the ICTs' infrastructures, by enlarging the areas of digital services available for customers and employees, as well as in the creation of a cultural background able to sustain the process of emancipation of the destination in a smart perspective.

In the scenario depicted by the data, starting any smart tourism initiative which point directly to the integration of the local supply, through the identification of managing players and/or the development of technological tools, risks encountering all the difficulties related to particular features of the context. Rather, what can and needs to be done as a first step in this context is to initiate a change management process aimed at creating, over time, the necessary cultural, organizational, and technological prerequisites for any further intervention aimed at developing and enhancing the competitiveness of the destination. Initiatives that are aimed at creating the necessary 'platform' of human, structural and social capital for transforming fragmented contexts into more structured and competitive configurations on which to develop more incisive actions, are necessary.

Furthermore, leveraging on the collaboration of nucleus of firms more prone on adopting new technologies, the creation of a regional agenda for the smart destination is mandatory for regional public institutions.

Their contribution has to be addressed toward a dual objective: to make available financial resources for the technological infrastructure as well as to create a digital culture more aligned with the emerging trends of the smart tourist. The effects and benefits in terms of competitive positioning reaped by this first nucleus is expected to drive the path of emulation by other companies, not only limited to the traditional tourist supply chain, but impacting on a wide larger community of local actors.

Abstract

Cash holding is a critical decision in any corporation around the globe. The ultimate objective of current study is to explore the cash holding determinants for making the decision in food industry of Pakistan. To obtain the objectives of current study data was gathered from the State Bank of Pakistan over a period of 8 years (2008 to 2015) of 39 food companies. The current study used correlation analysis, descriptive statistics and pooled ordinary least square regression model for analysis of selected firms. The empirical results of the research revealed that Cash flow; Leverage and Liquidity ratio observed a significant negative effect on cash holding. Moreover, profitability and size has significantly positive relationship with cash holding. Finally, the dividend policy and cash holding found to be insignificant positive association. The results of this study would help to the management for taking right decisions to keep optimal amount of cash holding.

Key words: Cash holding; Food industry; Pakistan; Decision making

1.0 Introduction:

Over the last two decades, nonfinancial companies accumulate large cash holdings around the globe due to expecting the crisis. In a period of crisis, external financing challenging and becomes more costly to gain in the tense economic markets. As a result, the firms try to build efforts to raise cash holdings to elude borrow external capital such as bank loan, equity offerings and bond offerings in reaction to the strain.

Cash provides liquidity and plays significant role in operation of firms. It is most significant part of an organization's assets. Organizations have stimulus to keep a cash to meet obligations, certain the operations and hold the beneficial investment opportunities Wai & Zhu (2013). In this way, cash management policies have become significant research area in the corporate finance studies in recent

years. However, for investment and operating capital needs firm must manage the effective liquidity position.

Keynes (1936) explained three objectives for why corporations might need to hold cash. These three objectives or motives i.e. the precautionary objective or motive, the transaction motive, and the speculative objective. In other words, The precautionary objective leads that companies keeps cash reserved in order to meet any future financing desires and the transaction objective leads that companies keeps cash for fulfilled their daily operations and also this level of cash will diminish the cost involved in the way of selling different other kinds of assets, while the speculative objective means that companies keep cash for achieve some interest income which investing in short-term interest-bearing assets, this liquidity could also be used to invest in future more profitable projects Al Zoubi (2013).

Theoretically, a firm has several reasons to hold cash. A typical motive are transaction costs Baumol (1952). For instance, taxes imposed on profits can be taken as transaction costs. This argument has been recommended by Foley, Hartzell, Titman, and Twite (2007). The second one called precautionary savings to entice firms to increase cash holding when external financing frictions make it hostile to take advantage of good-looking investment opportunities (Froot, Scharfstein, and Stein (1993)). Jensen (1986) suggested an agency motive that describes additional cash holdings.

Tahir, S.H., Sabir, H.M. and Shah, S.Z.A., (2011) studies the impact of earnings management on capital structure of non-financial companies listed on (KSE) Pakistan. They concluded negative effect of gearing ratio on return on assets. Again Tahir, S.H., Sabir, H.M., Alam, T. and Ismail, A., (2013) analyzed impact of firm's characteristics on stock return by using data of non-financial companies listed companies in Pakistan and revealed that market capitalization (MC) , earnings per share (EPS) and book to market (BTM) value found significant impact while sales growth had no effect on stock market returns.

The recent literature has enlightened the upsurge in aggregate cash-holdings both with a tax-based justification (Foley, Hartzell, Titman, and Twite (2007)), and a precautionary savings motive due to greater cash-flow unpredictability (e.g. Bates, Kahle, and Stulz (2009). Azar, Kagy, and Schmalz (2016) described variation in corporate cash-holdings to variation in the cost of carrying cash .Similarly, Curtis, C.C., Garın, J. and Mehkari, M.S., (2015) concluded that the changes in the real value of carrying cash when they argue that corporate cash holdings are negatively correlated with inflation. Graham and Leary (2015) found mixed evidence for precautionary saving motives and supported for a tax-based explanation for the increase in cash holdings using data ranging back to the 1920s.

Dittmar et al., (2003) explained that the agency costs of managerial prudence play much importance to explaining the cash holdings. With a sample of greater than 11,000 organizations from forty five countries, they found that organizations in these areas where shareholders rights are least protected keep twice cash as firms in countries with excellent protection of shareholders. Their substantiation is reliable with the speculation of that investors in countries with poor shareholder protection cannot force to managers for disgorge excessive cash balances.

1.1 Objectives of the study:

- To attain a relation between cash flow and cash holding of a firm.
- To obtain an association between size and cash holding of a firm.
- To find a connection between profitability and cash holding of a firm.
- To examine relation between leverage and cash holding of a firm.
- To analyze linkage between dividend policy and cash holding of a firm.
- To investigate relationship between liquidity and cash holding of a firm.
- To make policy recommendation to food industry of Pakistan.

2.0 Literature Review:

Cash is the vital liquid assets and is the concern to examine the firm's performance to pay its obligations in the long run. It plays critical role because it contributes high value to firms with extensive liquidity where firms are able to pay their outflows in time as if severe time's hit. To improve profits and sale, a firm needs to keep cash assets by supporting the future needs and adjust the level of optimist cash flow position. Therefore, cash is very important element for organizations to revitalization a business for long run in profitable ways.

Swain (2015) provided a critical analysis and reveled that cash holding are negatively connected to the size of a firm. Leverage could function as a substitute for an organization's competence to issue debt which proposed that highly leveraged firms have more capability to issue debt. Therefore an indirect relationship is expected among leverage ratio and the cash holding. Dividend paying firms have to maintain higher amount of cash holding for paying dividends. So, a direct linking exists among cash holding and dividend payment. Firms with unstable cash flows can suffer from cash shortage at any point of time. Cash shortage carries many costs to firm like foregoing attractive investment opportunities and costs of bankruptcy. More cash holdings are required to be sustained as a defensive to deal with such cash shortfall. So a direct relation is expected between degree cash flow capriciousness and cash holdings.

Pastor and Gama (2013) examined to focuses the driver of cash holding of Portuguese manufacturing small & medium firms for the period ranging 2001-2007. Empirical results disclosed that firm's size, liquidity, leverage, existing capital structure and association with improbability of cash flow had a significant influence at cash holding of manufacturing enterprises. Zoubi (2013) investigated the corporate cash-holding decision of non-financial firms in the time span of 11 years (2000 -2011) with a limited sample of eighty listed firms by using a panel data methodology. The results showed that firm size and growth opportunities have insignificant effect on cash holding, whereas firm's cash flow, leverage and current assets had a negative significant effect on cash holding. Moreover, dividend policy as well as profitability have a positive relationship at cash holding. They also examined a way of collection of descriptive measures effect firms' loan by concentrating on the liquid assets. The study also revealed that the debt ratio is positively linked by company's size and negatively associated with profitability, assets tangibility, growth opportunities, fixed assets and liquidity. The positive association of debt ratio through liquidity, non-tax shields, and debt ratio is positively associated by liquidity, non-debt tax shield, and company's size, tangibility of asset and cash ratio. Moreover, the long-term debt is negatively connected with profitability and growth. The negative association found of short term debt associated by tangibility of assets and company's size, cash ratio with its dissimilar ways.

Hasan, Mutairi, &Risik (2011) investigated the impact of financial performance and industrial sectors using the panel data of 80 listed companies in Kuwait. The results of this study suggested that converse to the financial theory of trade off as the negative association among debt and the financial performance. Mahajan & Chen (2010) found the cash holding of firms in thirty one non- European countries and fifteen European countries over the period of 10 years (1994 to 2004). They discovered that establishment of Economic & Monetary Union (EMU) and the introduction of the euro decreased cash reserving from the companies in areas of Europe. Moreover, they also exposed that companies keep too much liquidity as there is lot of opportunities of investment in the upcoming turnover and the firm's size had a positive link with cash ratio in the EMU. They claimed that current outcomes in response to the existence of cash flow had a positive relationship with cash ratio as companies which earn hand some income be liable to keep handsome amount of cash for the precautionary motives. The negative relationship among net working capital and cash ratio as it could be used as a liquidity standby. Cash holding have a positive connection with Capital cost as administrations are likely to keep up level of cash in the period of growth opportunities (GO). Leverage and cash ratio had a negative connection because availability of more debt could be considered a cash alternate. In addition, firms that paid dividends likely to keep higher level of cash in respect to deal this financial debt.

Ferreira & Vilela (2004) discovered the factors of cash ratio in EMU countries. Their study discovered that cash holding positively correlated with the cash flows and set of investment and leverage, size and liquidity had negatively linked with cash. Cash holdings and debts are negatively linked, which showed that a strong association with financial institutes allows the corporations to keep minimum amount of cash for protective situations. Organizations in good governance areas with concentrated ownership and better investor protection keep less amount cash.

García-Teruel et al., (2008) recognized a positive correlation among profitability cash ratio. They took cash flow as an independent variable and income as corporation which could envelope adequate level of cash flow from through its current operations can be measured excess organizations .Omet & Maghyereh (2002) also found that growth variable at Kuwaiti corporations and future' decision to keep cash was no significant effect. On the other hand, results also showed that debt has negative effect at corporations' cash holding.

3.0 Methodology of the Study:

To achieve the objective of study, secondary pooled data of 39 food companies were collected from the State Bank of Pakistan over the period of 8 years (2008-2015). The undermentioned dependent and independent variables were used in the study. Eviews was the software to be applied to draw the empirical results of the study.

3.1 Dependent variable:

Cash Ratio was the dependent variable used in the study. It was calculated cash plus cash equivalent. As literature had identified, many scholars and researchers calculated as same as current study calculated like as Ozkan & Ozkan (2004).

Cash Ratio (CR) = Cash + Cash Equivalents/Total Assets

3.2 Independent Variables:

Cash flow was calculate to add up the depreciation expense interest over total assets excluding cash. The same formula used by Mahajan & Chen (2010).

Cash flow (CF) = Earnings before tax + Depreciation/Total assets-cash

3.3 Return of Assets:

The return on assets (ROA) was used to measures the overall effectiveness of business in generating profits with its current available assets. Higher return on assets shows the efficient business operations and management to gathering the profit. The same measure also used by Titman and Wessels (1988).

Return on Assets (ROA) = Earnings after tax /Total Assets

3.4 Leverage:

Leverage is an advantageous technique which corporations get debts from financial institution of having a relatively small cost yield at a comparatively high level of returns. Leverage (LEV) was calculated as the total liabilities over total assets.

Leverage (LEV) = Total Liabilities over Total Assets

3.5 Dividends:

The dividend ratio is the amount of dividends paid to stockholders from the company. It has been measured as total cash dividend to total assets.

Dividend (DIV) = Cash Dividends/ Total Assets

3.6Liquidity (LIQ:)

Liquidity leads to liquid assets which could be converted quickly into cash with low impact on the received price. These assets were measured as NWC (net working capital) minis divided over total assets. Liquid assets also mean the ability of short term assets to pay its short term liabilities.

Liquidity (LIQ) = NWC – Cash over Total Assets

3.7Firm's Size:

The size of firm is calculated by the total assets and was measure as the logarithm of total assets of the company's. It's an independent variable of the study which means higher the firm size higher the profitability. The same measure was used by Ozkan & Ozkan (2004) and Ferreira & Vilela (2004).

Firm's Size = Ln (Total Assets)

3.8 Hypotheses:

H_1: *There is a significant negative association among company's cash holding and cash flow.*

H_2: *There is a significant positive link between company's size and cash holding.*

H_3: *There is a significant positive association between company's profitability (ROA) and cash holding.*

H_4: *There is a positive link among company's cash holding and leverage.*

H_5: *There is a negative association among company's dividends and cash holding.*

H_6: *There is a positive and significant link among firm's cash holding and liquidity.*

3.9 Statistical Model:

$$Cash_{it} = \beta_0 + \beta_1 CF + \beta_2 DIV + \beta_3 LEV + \beta_4 LIQ + \beta_5 ROA + \beta_6 Size + \varepsilon \quad (1)$$

Where:

Terminologies	Explanation
β_0	intercept of equation
β_1	coefficients of independent variables
I	No. of firms
T	Time periods
ε	the error term

3.0 Statistical Descriptive:

Table 4.1 indicated the number of observations for the whole research variables which is 312 for the period of study 2008 to 2015. The mean value of leverage is 59.96 which is highest value between all the independent variables of the research. Moreover, Size and return on assets have standard deviation and maximum values are 2.24, 11.25 and 17.74, 49.61 respectively. Standard deviation indicates the deviation of values from the average values. Meanwhile, the median of cash ratio is 1.88 and -1.80 for liquidity. The current study showed that the exploratory variables of the study are constant in the particular period of the research.

Table 1: Descriptive statistics

	Cash ratio	Cash flow	ROA	Leverage	Dividend	Liquidity	Size
Mean	5.64	12.71	5.115	59.96	18.86	-5.59	14.22
Median	1.88	9.08	4.141	68.85	6.86	-1.81	14.31
Std. Deviation	9.82	16.93	11.242	25.04	106.48	9.83	2.23
Minimum	1.62	-31.27	-30.83	22.64	5.810	-57.58	1.10
Maximum	57.61	83.30	49.61	120.60	809.460	9.110	17.74

Table 2: Correlations Matrices

	Cash Ratio	Cash Flow	ROA	Leverage	Dividend	Liquidity	Size
Cash Ratio	1						
Cash Flow	0.125*	1					
ROA	0.144*	.755**	1				
Leverage	-0.488**	-.166**	-.258**	1			
Dividend	0.03*	.233**	.214**	-0.069	1		
Liquidity	-.776**	.278**	-0.068	.343**	-0.038	1	
Size	-0.066	0.200**	.126*	.417**	0.034	0.002	1

*. Correlation is significant at 0.05 levels (2 tailed)
*. Correlation is significant at 0.01 levels (2 tailed)

For further analysis, correlation matrix estimates the relationship among two variables, whether they have positive, negative or no relation between dependent and exploratory variables. Table 4.2 showed the results of correlations for whole variables in the study. The value of cash ratio and leverage is -.488 which is negative and significant at .01 levels. Moreover, ROA and cash ratio value is .144 which is positive significant correlated at .05 levels. The value of correlation of cash ratio and cash flow is .125 which is positive significant at .05 levels. On the other hand, the correlation among size of the firm and cash ratio is negative but insignificant with value of -.066.

4.0 Empirical Results:

Table 4.3 explains the outcomes of pooled OLS regression model for the sample of 39 corporations of food industry. The outcomes of OLS described that model is significant at the levels of 5% with 124.32 F-statistics. The adjusted R squared is higher at 70% value which means the independent variables were explained 70% of the dependent variables. Further explanation of variables, cash flow has significant negative coefficient with the dependent variable for the research. Which means cash flow and cash ratio have negative relationship with each other's? This result also matched by Ozkan & Ozkan (2004).

Table No 3: Regression Results

	Pooling OLS
β_0	0.0507*(3.8735)
$\beta_1 CF$	0.0000***(-0.2159)
$\beta_2 DIV$	0.8759(0.0004)
$\beta_3 LEV$	0.0000***(-0.0909)
$\beta_4 LIQ$	0.0000***(-0.7782)
$\beta_5 ROA$	0.0000***(0.2640)
$\beta_6 Size$	0.0592*(0.2993)
R squared	0.709794
Adjusted R squared	0.704085
F statistic	124.3297
(P value)	0.0000

(Where cash ratio is dependable variable and CF, DIV, LEV, LIQ, ROA and Size are independent variables. The coefficients numbers are in the brackets, ***, **,* showed coefficients are the 1%, 5% and 10% levels significant respectively for the period of 2008-2015).

The dividend ratio has positive and insignificant association with cash ratio, when the corporations pay dividends than they require to keeping high amount of cash. Many research also found same outcomes like Mahajan & Chen (2010). Leverage has significant and negative association with cash

ratio. The result also matched with Ozkan & Ozkan (2004). Moreover, liquidity has a negative and significant association with cash ratio, it means when corporations have high liquidity than they tend to keep less amount of cash. Al Zoubi (2013)also found same result. Return on Assets has significantly positive relationship with cash ratio. This positive association also described by the pecking order theory. Ferreira & Vilela (2004) also have same outcomes. Firm's size has significant positive connection with cash ratio for food industry. It means larger corporations need to hold more cash as smeller and also have higher profitability. Many other researchers have same results such as Almazari (2014), Pastor & Gama (2013).

4.0 Conclusions:

The research was conducted on food industry listed at Pakistan Stock Exchange to explore the determinants of cash holding. To achieve the objectives of current study, pooled data were collected form the of State Bank of Pakistan. A sample of 39 companies from food industry was taken to analyze the data with the help of pooled ordinary least square. The empirical results showed that coefficient of the cash flow has significant negative effect with the cash ratio or vice versa. It means the firms have higher level of cash flow keep lower level cash holding. The results were consistent with Ferreira, M.A. and Vilela, A.S., 2004. Moreover, Moreover, Return on Assets (ROA) has significantly positive relationship with cash ratio. It was concluded the firms having higher level of profitability maintain higher level of cash in company account. These results were in line with the study Mirza, H.H. and Azfa, T., 2010.

.Liquid assets have a significant negative association with cash ratio. It means high liquidity tends to low quantity of cash. If the firm has high level of current assets then lesser need of cash to maintain the operation of corporation. The results were consistent with the conclusion of Ozkan, A. and Ozkan, N., 2004. Similarly, Size of the corporation has significant positive effect on cash-holding for food sector of Pakistan. The study outcomes showed that many insights on the cash holdings decision in Pakistan. Finally, the study recognized the main key players that had been overlooked by the food industry of Pakistan.

5.0 Limitations:

The following limitations are measured:-

1. The results are of some of listed firms and non-listed firms are not integrated.
2. In relation to the factors concerning with corporate cash holding has not been done by a self-determining research. In addition, research was related to corporate cash holding because there is a lack of research work in this ground of study sources in Pakistan.

A Theoretical Analysis of Factors Influencing the Decision of Faculty to Use Educational Technologies in the Context of Institutions of Higher Education

Mohammad Ayub Khan, Tecnologico de Monterrey, Campus Monterrey, Mexico
mkhan@itesm.mx
Amina Omrane, Assistant-professor (HDR) at FSEG-Sfax and researcher at ECTSRA, IHEC-Carthage, Tunisia
amina.omrane@yahoo.fr
Adriana Morales Rodríguez, Tecnologico de Monterrey, Campus Tampico, Mexico
adrianamorales@itesm.mx

Abstract

In this paper we study factors influencing faculty's decision to use educational technologies to support their pedagogical strategies. We briefly describe educational technologies commonly used by faculty to support teaching such as emails, video conferences, chat rooms, video lectures, blackboard discussions and Power Point Presentations for example. We explain in detail faculty factors (i.e., gender, age and cultural background), student factors (i.e., academic performance and gender) and contextual factors (i.e., classroom size, institutional support, course subject, and time constraints) as influential factors in using educational technologies by the faculty to support teaching. The paper findings suggest that the factors under study do influence the faculty decision to use educational technologies to support teaching, however, there are certain strategies education institutions can rely upon in order to overcome the barriers that discourage the faculty to fully integrate technology into their pedagogical strategies.

Keywords: Education technology, faculty decision to use technology, higher education, Instructional technology, pedagogical strategies, teaching styles and technology.

Introduction

The importance of information and communication technology (ICT) in the evolution and revolution of the modern education system is an undisputable phenomenon. ICT has helped in generating, preserving and disseminating knowledge and at the same time improving human abilities to share knowledge and experiences (Afshari et. al., 2009). ICT helps people access, gather, analyze, present, transmit, and simulate information (See, 1994). ICT creates a learning environment where students deal with knowledge in an active, self-directed and constructive way (Webber, 2003). ICT can develop student's skills for cooperation, communication, problem solving and lifelong learning (Voogt, 2003). Education institutions should prepare students to make effective use of technology which they need in the 21st century (Middleton & Murray, 1999) not only in the workplace but in all walks of life. For graduates to be successful in the current and more in the future work environment, educational institutions must make technologies of information and communication available to students since most of such technologies are already being used in the business world (Davis, 1989). When refereeing to the educational technologies or pedagogical technologies (i.e., technology used to teach and learn) faculty members have a variety of options available for them to support teaching but ironically there certain barriers which limit them to do so (Grasha & Yangarber-Hicks, 2000).

Over the past several years the emergence and the use of educational technologies have been on the rise (Downing & Garmon, 2001). This trend has forced universities to increase substantially their investments in educational technologies, technology experts and faculty training as never before. In parallel to the changes brought about by new technologies in the field of education, researchers have become equally

concerns about the actual and potential benefits of integrating technological supports (i.e., the use of software, online discussions and chats; Facebook, Twitters, emails, course websites etc.) into other pedagogical strategies such as case studies, research, problem solving and project management (Grasha & Yangarber-Hicks, 2000). Cuban (1999) is of the view that professors and students are getting used to educational and communication technologies of e-mails and Web pages, but few of the faculty use these technologies for teaching purposes. Even those professors who use technology still face several barriers such as inadequate availability of technology and classrooms that do not support technology (Brill & Galloway, 2007). Simply using whiteboards instead of chalkboards, PowerPoint instead of overhead transparencies, and electronic communication instead of office hours have implications for the faculty (cultural, work habits, work system) for teachers (Katz, 2006). There can be positive outcomes of the use of technology for educational purposes in many ways. For instances, it can improve communication between the teacher and students (Flanagin & Metzger, 2001) and thus, enhancing student-teacher interactions (Waldeck, Kearney & Plax, 2001). Technology can also make it much easier for students to have access to the required educational information cheaply, easily, and timely (Panici, 1998). The use of technology for education purposes may also affects positively student outcomes such as cognitive, behavioral and affective learning (Witt & Wheeless, 2001). But faculty to a large extent, still resist the full technology-pedagogy integration to this date.

Given the fact that the faculty´s resistance to embrace technology fully for teaching purposes is still a big challenge in the educational institutions of higher education, there is the need for a broader and exploratory research to study all those factors which potentially influence the decision of the faculty to fully integrate educational technologies into their pedagogical strategies. Therefore, this particular study is dedicated to the identification and analysis of those factors which influence the faculty to use pedagogical technologies to support teaching. The findings of the study will help the academic leadership of the institutions of higher education to consider those factors while developing curriculum, pedagogical strategies and faculty development programs. Especially, the outcome of the study will be useful when educational technologies are embedded with the existing pedagogical strategies to teach bricks and mortar classroom.

Literature review

The literature review focuses technological platforms that are available for the university faculty to choose from as educational technologies (ET) and explains factors influencing the decision of the faculty to use technology for teaching purposes, as shown in figure 1. The literature review also explains educational strategies (pedagogical approaches) and the integration of educational technologies and educational strategies.

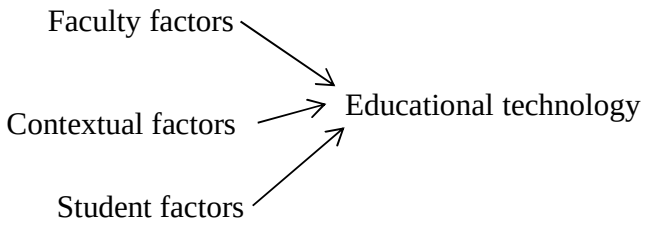

Fig.1: Factors Affecting the Decision of Faculty to Use ET

Educational Strategies

Educational institutions are responsible for developing competencies (Knowledge, skills and values) in students who will become future leaders (Alon & McIntyre, 2005). In order to achieve or fulfill this

responsibility educational strategies (pedagogy) require combining different teaching mechanisms ranging from lectures, classroom interactions, case discussions, simulations, experiential methods, team projects, and report writings (Vance, 1993). The pedagogy of education should include action learning model, the critical reflection learning model, the experiential learning model and service learning project (Holman, 2000). Educational strategies should also include finding out an optimal combination of the different teaching styles such as conceptual versus practical, individual versus collective, and under instruction versus via self-study (Boisot & Fiol, 1987). Ulrich (2005) grouped the educational strategies into four general categories: instructor-centered strategies, interactive strategies, individual-learning strategies, and experiential-learning strategies. The instructor-centered strategies rely on one-way communication where information is provided from the instructor to the students through lecture. Lectures are particularly efficient and effective for large classes and for instruction at the lower levels (knowledge and comprehension) of the cognitive domain (Weston & Cranton, 1986). Interactive strategies use two-way communication between the instructor and students as well as among students. More importantly, with such approaches students have an opportunity to participate actively in the learning and teaching processes. Interactive strategies include small group discussions, cooperative learning, group projects, argumentative discussion, large-class discussion, and seminars (Ulrich, 2005). Individual-learning strategies allow students to learn at their own pace through regular immediate feedback in order to assess their progress. Individual-learning strategies are examinations-in-general, problem examinations, term papers, homework, required readings, and thinking alone (Ulrich, 2005). The experiential-learning strategies are active learning because students take an active role in reaching the more complex educational outcomes of application, analysis, synthesis, and evaluation (Chickering, 1977). Experiential-learning strategies include: internships, management simulation, role playing, structured experiential exercises, videos, case analyses, and case studies (Ulrich, 2005). Any of these teaching and learning strategies, if supported appropriately and adequately by the use of educational technology, the purpose of education, which is graduating students with competencies in their respective fields and disciplines (knowledge, abilities and values) needed in the society and industry, is possible to achieve.

Educational Technologies

Defining the term educational technology (also known as instructional technology) is difficult since there is a need to distinguish between educational technology as a theory and as a field of practice and to focus on either the process or the system approaches (Al-Ammary, 2013). The educational technology is defined as solutions to instructional problems involving social as well as machine technologies in order to improve the effectiveness and efficiency of learning in the context of education (Gentry, 1995). The educational technology is also considered as means of media with four different focuses: media for enquiry (i.e., data modelling, spreadsheets, hypertext, etc.); media for communication (i.e., e-mail, graphics software and simulations); media for construction (i.e., robotics, CAD, control systems), and media for expression such as interactive video, animation software, music composition (Bruce & Levin, 1997). Many in the education industry view education technology as a tool for improving the presentation of material for making lessons more fun for the learners and for making administration more efficient (Cox et al., 1999). Furthermore, education technology is defined as “the study and ethical practice of facilitating learning and improving performance by creating, using and managing appropriate technological processes and resources (Richey, 2008)”. Educational technologies are also defined as the theory and practice of design, development, use, management, and evaluation of processes and resources for learning (Richey, 2013). Educational technologies are the hardware and software packages that provide a mechanism for delivering instruction and needed instructional support for teachers and students (Rice & Miller, 2001).

The educational technology is useful both for the educators and educational administrators. The emergence of different educational tools and software has motivated educational institutions to integrate them into the educational strategies (Hawkins et al., 1996). Educational technologies are considered crucial for improving the quality of education in general and enhancing the level of student learning performance (Bialo & Sivin-Kachala, 1995) in particular. Technology has solved the problem of distance,

time and finance and created a situation where effective and productive learning philosophies got grounds. Higher education's competitiveness will increasingly require that it serve society's needs and the enablement of its missions through information technology and that the campus of the future will embody distributed learning (Oblinger & Maruyama, 1996). Educators and policy leaders are envisioning new approaches to instruction based on communications and computer technology using learning on demand and learner-centered instruction (Twigg & Oblinger, 1997).

Faculty members have a wide range of educational technologies available for them to use in support of the traditional methods of teaching (Boose, 2001). For example, instructors may use PowerPoint presentations, or organize video conferences in order to bring guest lecturers from distant places into the classroom or simply using YouTube lectures to support class lectures. Faculty can also use other computer-based technologies such as electronic mail, Web pages, chat rooms, and electronic bulletin boards to facilitate communication with the students (Driver, 2002). Social networks such as Facebook, Twitter and LinkedIn are also popular among the young generation to share information and communicate interactively. A number of other teaching software, online exercises, interactive televisions and computer simulations are available for faculty members to use (Seay et al., 2001). Table 1 provides a list of information and communication technology tools used in teaching and learning in educational institutions of all categories and sizes (Thieman, 2008).

Table 1: List of ICT to use as Educational Technologies

LCD Projector	Word Processing	Computer Games
DVD/Streaming Video	Internet Search Tools	Digital/video Cameras
Tape/CD player	Graphic Organizers	CD's of student work
Graphics Clip/Art	Web-quests	Spreadsheet
CD-ROM	Webpage/Class websites	Power Point
Smart Board	Subject specific software	Web Log
I-Movie	Podcasts	Email
Photo Shop	Simulations	

Integration of Educational Technologies and Educational Strategies

The use of educational technology in support of teaching enhances learning and benefits students (Kim & Hannafin, 2011). However, most teachers do not fully and effectively integrate technology into teaching strategies (Gorder, 2008) rather they only use educational technology to design instructional materials or deliver lectures (Tondeur, van Keer, van Braak, & Valcke, 2008). The faculty has a variety of technology options to select from to support their particular teaching strategy. Also, faculty has the option to use the technology according to their needs and interests starting from the basic uses (power points presentations and sending emails for example) to the very advanced or well-integrated level (online learning). In any of these levels of technology-pedagogy integration, it is important that two basic educational elements which are content and pedagogy (teaching and learning) must be assisted by the use of educational technologies, not otherwise (Earle, 2002). Educational technologies should be a hindrance neither for the teacher nor for the students (Earle, 2002). An effective and purposeful integration of educational technologies and educational pedagogy must encompass (Tondeur, van Keer, van Braak, & Valcke, 2008):

1. Encouraging collaborative learning through information search on the Internet and sharing information.
2. Using computers for differentiating and creating learning activities.
3. Encouraging students to improve their skills (i.e., information literacy and management).
4. Requiring students to conduct research projects and other learning activities using computer and computer related technologies.
5. Using computer as a pedagogical platform (i.e., instruction and demonstration tool).
6. Teaching students about the possibilities and potentials of computer use.

Educational technologies should encourage students to participate in learning tasks, including collecting, analyzing, and presenting information (Niederhauser & Stoddart, 2001). The integration of educational technologies into pedagogical strategies should go beyond only facilitating student development of conceptual understanding through instructional processes to active teacher-student engagement in learning through learner-centered teaching approaches using for example, project-based learning and collaborative learning (Inan, Lowther, Ross, & Strahl, 2010). Existing studies (i.e., Yen & Lee, 2011) show that students using technology for classroom group discussions and report writings perform better in terms of learning achievements (academic performance) than those students who do not use technology for learning purposes. Instructors using technology to support their teaching ought to act as coaches, facilitators, mentor and guide (constructivist approach) rather than acting like traditional lecturers (instructor-centered teaching). Students should be allowed to use in-depth questioning to acquire information, work in small groups, interact and develop their verbal and social skills (Nussbaum et al., 2009).

Factors Influencing Faculty´s Decision to use Educational Technology

Well integrated pedagogy-technology educational system and culture is fundamental for the provision of quality education now and in the future. Since, educational technologies are the recent inventions, adoption of which by the faculty to support their teaching demands a gradual approach and creative-conducive work environment. It is also important to identify and study those factors which influence or might influence positively or negatively the decision of the faculty to use educational technologies. As suggested earlier the term educational technologies or ICT refers to computers and the associated hardware, networks, and software used and could be used for teaching and learning purposes. The use of educational technologies to support teaching can be affected by several factors such as social contexts and appreciations of usefulness of technology in teaching (Zare-ee, 2011). Factors like lack of necessary resources for the faculty and negative attitudes and beliefs of the faculty are also found some of the main causes for the insufficient technology-pedagogy integration (Park & Son, 2009). Ertmer (1999) identified and categorized barriers which influence the decision of faculty to use technology as external (lack of equipment, insufficient training and lack of on time-technical support) and internal (teacher beliefs and attitude) barriers. Several other factors influencing the adoption and integration of ICT into teaching have been identified by researchers. For example, Stockdill and Moreshouse (1992) identified user characteristics, content characteristics, technological considerations, and organizational capacity as factors influencing ICT adoption and integration into teaching. Balanskat, Blamire & Kefalla (2007) identified the factors as teacher-level, school-level and system-level. Teachers' integration of ICT into teaching is also influenced by organizational factors, attitudes towards technology and other factors (Chen, 2008). Sherry & Gibson (2002) claim that technological, individual, organizational, and institutional factors should be considered when examining ICT adoption and integration. Neyland (2011) found factors such as institutional support as well as micro factors such as teacher capability of using computer and computer related programs influencing the use of online learning. Ahadiat (2005) added ethnicity, rank, sub-areas, as influential factors in using instructional technology by the instructors. Teachers' characteristics (e.g. individual's educational level, age, gender, educational experience, experience with the computer for educational purposes and financial position) were found influencing the adoption of an innovation (Schiller, 2003) or new system of work. In addition, Bauer and Kenton (2005) found that students´ factors such as they did not have enough time to go to computer labs or work with computers and teachers needed extra planning time for technology lessons. Other concerns were outdated hardware, lack of appropriate software, technical difficulties, and student skill levels affect the use of educational technologies at school. According to Carvin (1999) "The teacher's own learning style is certainly one such factor. For example, if a teacher is a creative thinker who likes the idea of constructing knowledge, is a life-long learner, a social learner, and a decision maker, he may be more likely to use computers in more integrative and transformational ways that are useful and valuable to students instead of ways that promote and support traditional classroom practices".

Table 1 list factors that influence faculty decision to use educational technologies to support teaching and learning (Medlin, 2001; Al-Bataineh et al. 2008; Yildirim 2007; Frederick, Schweizer & Lowe 2006;

Goktas, Yildirim & Yildirim 2009; Lim & Chai, 2008; Fu, 2013; Iniesta-Bonillo et al., 2013; Cooper, 2006; Peluchette & Rust, 2005):

Table 2 List of Factors Influencing Faculty Decision to Use Educational Technology

Pedagogical support	Reward system
Skills for managing teaching materials	Mandate & recognition
Software competence	Class Size
Excessive focus on teaching technical or operational skills rather than course content	Course/subject nature
	Resources (time and money)
In-service training on the use of ICT	Student abilities
Technical problems in the classroom	Problems with technology
Uncertainty about the possible benefits of using ICT in the classroom	Infrastructure
	Need for the technology
Lack of specific direction	Technical support and facilities
Faculty gender	Teaching experience with ICT
Area of expertise of faculty	Availability of enough computers
University of origin of faculty	Time constraints
Student factors	Social pressure
Institutional factors	Personal interest
Technology related factors	Individual behavior
Faculty experience	Teacher expectations
Individual culture	Clear goals for ICT use

Other human factors such as individual feelings of anxiety, fears, preferences and perceptions, feelings of competence, and teaching styles and strategies of the professor have also been correlated with the decision of using instructional technologies (Dusik, 2000). Robertson et al (1996) argued that teachers' resistance to computer use was divided into several broad-based themes: resistance to organizational change; resistance to outside intervention; time management problems; lack of support from the administration; teachers' perceptions; personal and psychological factor. Researchers (Osika, 2006) are of the view that if proper and early attention is given to these diverse beliefs and competencies of the faculty, there will be a strong likelihood that the faculty will opt for integrating instructional technologies into their teaching strategies.

Given the fact that there are diverse and multidimensional factors that influence or can influence the decision of the faculty to use educational technologies in their classes, this paper focuses on factors as shown in Figure 2:

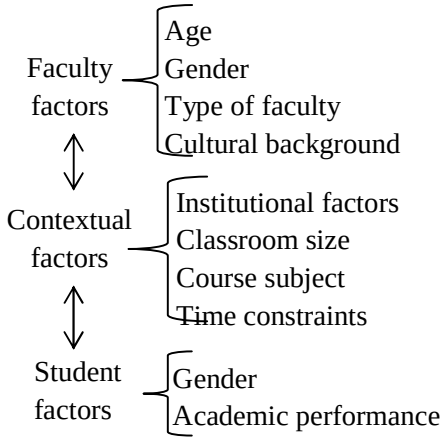

Fig.2: Faculty, Contextual and Student Factors Influencing the Use of Educational Technologies

Faculty Factors: Faculty factors including individual's educational level, age, gender, educational experience, and experience with the computer are found to influence the adoption of an innovation (Schiller, 2003) or innovative system such as instructional technologies. For example, faculty members with fewer years of experience are more likely to use computers in their classes than teachers with more years of experience (National Center for Education Statistics, 2000). This is possible due to the fact that the faculty is new to use the computer and generally new faculty members are provided training to use computers as a part of their orientation programs. The age factor of the faculty is found to be an influential factor as well in the decision-making process of whether to integrate educational technologies into teaching strategies. Faculty who are in the middle or later stages of their careers can resist the use of instructional changes since tenured faculty may not be compelled to use technology and senior faculty may not have the knowledge or required training to use the educational technology (Peluchette & Rust, 2005). Other studies found that different types of faculty view differently the use and importance of technology for teaching purposes. Al-Bataineh and Brooks, (2003) identified these 5 different types of faculty and their corresponding characteristics in relation to the computer efficacy and the use of educational technology for teaching purposes:

1. Knowledge-level teachers aware of computers and may be users or non-users. They are capable of following well-written key-by-key directions.
2. Application-level teachers are willing to use or allow students to use applications, but leave instructional control with the software.
3. Analysis-level teachers are capable of extracting portions of applications to assist in student achievement of identified curriculum objectives.
4. Synthesis-level teachers merge classroom instruction, relevant on-line instructional techniques and supplementary materials.
5. Evaluation-level teachers create and appraise classroom opportunities for learning beyond the design of instructional software and accompanying curriculum materials.

The relationship between gender and the use of technology is a popular discussion within the research community. For example, women's use of the telephone for socialization purposes helped expand this usage in both residential and business areas (Martin, 1991). The importance of gender and technology association study is encouraged since it is important to learn how new technologies are evaluated through the lens of an existing gender system (Hopkins, 1998; Hopkin, 1997). There are emotional, psychological, social reasoning behind the differing views of men and women of the use of computers in personal and professional life. There are differences on how do men and women view the world. Men tend to see the real world as a hierarchical structure whereas women tend to view it as an interconnected web of people (Gilligan, (1982). Therefore, for example, e-learning, which integrates computer and communication

technology, might affect men and women differently because of the communication patterns adopted by them (Heinich et. al., 1996). In another study, women and men were found to have different beliefs of usefulness and the ease of use of email (Gefen & Straub, 1997). According to Spotts (1997), male faculty members tend to rate their knowledge and use of technology higher than their female counterparts. However, female instructors take factors such as lack of time and lack of professional advancement into consideration when deciding whether or not to integrate technology into the curriculum. Additionally, Lumpe and Chambers (2001) argue that female instructors believe that factors such as administrators, students, equipment, and professional development, directly influence a person's ability to be successful with technology. Gender differences are also found in adopting new software systems where men technology acceptance is affected by their perception of usefulness, while women are influenced by perceptions of ease of use and subjective norms (Venkatesh & Morris 2000).

Moreover, studies on the cultural background of the faculty have shown that the individual cultural backgrounds can be a driving force when accepting a change or a new work system in the workplace. In the education field, socio-cultural background of faculty can be an influential factor in accepting or rejecting the use of a particular instructional technology (Cuban, Kirkpatrick, & Peck, 2001; Huang, 1997. For example, a study (Zare-ee, 2011) on education issues in Turkey finds that oral tradition and patronage system combined with the rote memorization and the sacredness of the text, make online textbook less suitable. Also, in societies where interpersonal relationship with relatives, family and neighbors is superior to individual independence and self-reliance, faculty will tend to prefer face-to-face and more personalized teaching and learning strategies (Zare-ee, 2011). In cultures where teachers use textbook as a source the primary source of knowledge and consider correct answers or high scores on paper-pencil tests when assessing learning success (Lee, 2009) may not opt for the use of online or computer-based exams for example. Similarly, in cultures where teachers are expected to cover the textbook of the course as a whole as a source of good academic achievements and performance leading students to high school or university entrance (admission), faculty members tend to cover the textbook content to guide student learning and thus affecting the use technology (C.-H. Chen, 2008). Computer based collaborative works at student and classroom levels have also been shown to affect the role of teachers and expectations of the learners and thus creating a new dynamic of teaching-learning environment (Damarin, 1998). Other researchers (i.e., Reeves & Reeves (1997) foresee the core pedagogical values might be considered appropriate in one culture but inappropriate in another, for example, "the expectation that students will question knowledge, or challenge the teacher's view". More so, "when teachers are overly concerned with academic achievement and skill-based knowledge, and teach textbook content only, or identify with the examination-oriented education culture, technology integration would be insufficient and lack meaningful practices; this may be related to an inadequate understanding of technology integration (Liu, 2010)". Therefore, Henderson (1996) suggested that instructional design models must include cultural contextuality in addition to the cognitive, social and pedagogical issues and "instructional design is about the creation of cultural identity and cannot be culturally neutral".

Contextual Factors*:* The contextual factors that influence or might influence the decision of the faculty to use educational technology for teaching purposes include institutional factors, classroom size, course subject, and time constraints. Institutional factors include a wide range of factors such as faculty development programs, ease of access to use technology, policies and procedures, and support for technological (Osika, 2006). Institutional support include accessibility; technical support; leadership support; professional development, teaching workload; teaching experience (Buabeng Andoh, 2012). The role of the classroom size assigned to the faculty as a contextual factor is also important in the implementation of educational technologies by the faculty. For example, when faculty members use technologies such as email and chat rooms, large classes can be difficult to manage, especially when teaching an online course (Peluchette et. al., 2005). Though there is no answer to the question of what is the ideal size of the class (Kelly & Maushak, 2004), pedagogically it is relatively easier for the faculty to work with a small size classroom when implementing new technology or pedagogical strategies (Maushak, Kelley & Blodgett, 2001).

Another contextual factor which is the course subject (or the course taught by the faculty) is also influences the choice of technology used to support the learning experience. Related variables such as the learning objectives of the course, textbook and other course materials to be used for teaching (Mumtaz (2000) are also important to consider. For example, faculty teaching soft subjects like strategic management and marketing courses may use computer and related software in class to carry out simulation and other group dynamics. But faculty teaching more quantitative and complex courses (i.e., from engineering and medical fields) tend to depend more on traditional pedagogical strategies in order to interact more directly with the students. On the top of these contextual factors described above, lack of time (time constraints) has been found one of the critical factors in influencing the decision of the faculty when using technology to support teaching (Mumtaz, 2000). Lack of time includes both the release time and the scheduled time (Mumtaz, 2000) where both the lack of release time and the scheduled time are found not allowing faculty to use computers in their classes, prepare materials for their classes and practice computers and software. For course development, course management and technology related training faculty requires sufficient time (Bocchi et al., 2004) out of their regular workload. "Teacher's time committed to teaching and amount of technology training are reliable factors of technology use in classroom (Vannatta & Fordham (2004)".

Student Factors: Students factors including academic performance of students, gender, age, academic background, professional experience, ethnicity, socio-economic conditions, nationality and computer self-efficacy are influential factors in the decision of faculty to use instructional technologies in their courses/classes (C-H. Chen, 2008). However, this paper focuses on the academic performance and gender of students for further elaborations. In fact, the pedagogy-technology integration should promote active learning and thus benefiting students by improving their learning and academic achievements (Liu, 2007). For such an active learning to happen, students must participate actively in the learning process and perform well academically. Li (2007) wrote "that if teachers had poor students or were teaching unfamiliar subjects, technology use was not considered, even when teachers understood that students favored technology and technology was the preferred means of acquiring information". In addition to the academic performance of students, the role of gender (female vs male students) of students is also an important criterion for the faculty to use educational technologies. Historically the use of technology is considered as being a male activity (Wajcman, 1991). A study on the gender issue by Shashaani (1995) finds that male students have not only interest in learning and using computers but they also receive encouragement to use computers. Another study of Macleod, Haywood & Haywood (2002) suggests that female students are relatively more apprehensive about computer use and view technology more favorably than their male counterparts (students). Contrastingly, some other studies find that females generally feel more anxiety and less experience with technology than males (Ayersman & Reed, 1995). "Males typically have lower computer anxiety and higher computer interest than females (Schumacher & Morahon, 2001)".

Discussion and Conclusion

The information and communication technologies have brought dramatic and revolutionary changes in all walks of life of human societies and more notably in our education system (Buabeng-Andoh, 2012). Technology has affected and is affecting at the skyrocketing speed the workplace, business and business management, organizations and our individual life. In response to such trends and tendencies our schools and universities are expected to reorganize and reorient their educational programs and services including curriculum and pedagogical strategies. The gap between teaching and learning must be bridged through an effective adoption of the advances in the educational technologies in order to provide learners with knowledge of specific subject areas, to promote meaningful learning and to enhance professional productivity (Tomei, 2005). One must consider the potential benefits of the use of educational technologies to support pedagogical strategies as listed by Becta, (2004): Increased academic achievements; encourages student's collaboration; improves student's communication and interpersonal skills (e.g., ability to be a group member); increase the competency among other academic staff; give the teachers the opportunity to be learning facilitators instead of information providers. Reduce the pressure

of the lecture preparation on the instructor; make the content and delivered materials of the lectures clearer; helps the students to remember the information easily; increases the interaction between students; and, enhances the students' ability to work in a group.

However, a number of factors associated with the faculty, institution, and student make it difficult for the educational technologies to be well- integrated into the existing teaching and learning strategies in the institutions of higher education (Bauer & Kenton, 2005). Teacher-level barriers include lack of teacher ICT skills; lack of teacher confidence; lack of pedagogical teacher training; lack of follow-up of new and lack of differentiated training programs. Faculty factors include beliefs about what (content) and how (pedagogy) to teach and skills including classroom management, teaching skills and computer handling. Also, matching the instructional technology with pedagogy used in teaching a particular subject is an influential factor in the decision of the faculty to use educational technology (Franklin, 2007). Other factors such as feelings, knowledge and attitudes of the faculty influence the use of educational technologies in teaching (Huang & Liaw, 2005). Moreover, faculty perception of the use of technology as better than previous practice; consistent with their existing values, past experiences and needs; ease to use, can be experimented with on a limited basis before making a decision to adopt and finally the results of the innovation are visible to others (Keengwe & Onchwari, 2008). Institutional factors such as technical support, funding, training and facilities influence faculty adoption and integration of technologies into their classrooms (Wozney et al., 2006). The school-level barriers comprise absence of ICT infrastructure; old or poorly maintained hardware; lack of suitable educational software; limited access to ICT; limited project-related experience; lack of ICT mainstreaming into school's strategy and the system-level barriers include rigid structure of traditional education systems; traditional assessment; restrictive curricula and restricted organizational structure. Knowing the extent to which these barriers affect individuals and institutions may help in taking a decision on how to tackle them (Becta, 2004). The general perception felt on campus among the faculty and students alike is that the computers and related technologies are logistical burdens and barriers for the effective teaching and learning in that both faculty and students spend time in learning how to use the technology. Technological platforms are changing without giving the faculty and student enough time learn and take fully advantage from one technology before opting for adopting a new one (Plair, 2008).

Recommendations and Implications

As concluded that the educational technologies are parts and parcels of the education system and there is no way to deny the use of educational technologies in one way or the other. Nonetheless, it is also concluded that there is still resistance from different forces within and without the education institutions to fully integrate educational technologies into the regular pedagogical strategies across the board. Therefore, herewith a number of practical recommendations are put forward for the educational institutions and their leadership to pursue while trying or wanting to adopt educational technologies to support pedagogical strategies. (1) Faculty attitude must be changed from negative to positive towards technology and the uses of technology for teaching purposes. They must be assured that technology will make their teaching interesting, easier, fund, motivating and enjoyable (Bruce & Levin, 2001). (2) Faculty should be made aware that the use of technology in teaching is helpful for the students alike since it encourages inquiry, helping communication, constructing teaching products, and assisting students' self-expression (McCannon & Crews, 2000). (3) The issue of the use of technology and its usefulness must be part of programs of faculty development and when discussing instruction, education, or training issues (Snelbecker, 1999). (4) Faculty perception of the usefulness of the technology should be improved and the constraints of self-efficacy and structure must be removed (Buchanan et al., 2013). (5) Educational institutions must remove or at least reduce the barriers: Lack of time to integrate educational technology in teaching activities; lack of funding to purchase the equipment and software needed; insufficient computing infrastructure (servers, bandwidth, storage capacity; Insufficient computing facilities (labs, technology-equipped classrooms; not enough training offered in the areas that interest you; not enough assistance with technical problems; not interested in using technology (Fu, 2013). (6) Provide trainings and workshops related to technology to update teachers' skills and knowledge (Al-

Bataineh et al. 2008). (7) Support partnerships that help teachers share effective technology practices and experiences (Ertmer & Otternbreit-Leftwich 2010). (8) Augment curricula with technology-enhanced materials (Goktas, Yildirim & Yildirim 2009). (9) Provide enough freedom for teachers in selecting and covering curriculum material (Honan 2008). (10) Provide adequate technical support to the faculty and students (Liu & Szabo 2009).

However, the implementation task of such recommendations is not without limitations (Gilakjani, 2013). *Firstly*, the use of instructional technology alone does not guarantee the effective use of the technology for teaching purposes. *Secondly*, there is need for proper planning, implementing and evaluating the technology-pedagogy integration work. The use of technology in teaching should enhance both the quality and productivity of the education services provided to students. Achieving optimal conditions for faculty, students and the institution to integrate and maintain the technology-pedagogy integration is pivotal. It demands time, money, culture and strategy from the academic leaderships. It is also imperative to provide enough time, financial assistances, technical help and pedagogical guidance to the faculty in order to design teaching activities and experiences supported by technology; implement such activities as planned and assessing the effectiveness of technology based teaching. *Thirdly*, as suggested by researchers in the field (i.e., Gilakjani, 2013), faculty will have to understand and be responsible for the social, ethical, legal, and human issues in connection with the technology-pedagogy integration. *Fourthly*, exercising extreme patience from all the concerned corners is needed since integrating technology-pedagogy fully and truly is a slow and time-consuming process and task (Collins, 1997). *Fifthly*, continuous collaboration from and good communication among the institutional leadership, faculty, students, technology support center and pedagogical specialists will enable the technology-pedagogy integration process and system to function smoothly and properly. For this to happen, all relevant stakeholders need to meet regularly to share best practices and on time information (Usun, 2005). The technology-pedagogy integration management should include faculty evaluation and feedback on how did they use technology in their classes and the impact of the same on their teaching effectiveness (Dahlstrom, 2015). *Sixthly*, it is also a cumbersome task to identify and match differing variables such as new advances in educational technologies, nature of the course, learning outcomes of the course, lecture type and materials, students learning styles and professors´ teaching styles (Trucano, 2005). Additionally, institutions of higher education must make the adoption of new technologies to support pedagogical strategies, an important component of the institutional strategic planning. *Seventhly*, and finally, the macro environment (society, industry and technology) surrounding organizations is constantly changing and thus demanding for permanent need assessment methods, change strategy, new organizational system (Balash et al., 2011), culture and strong leadership.

Limitations and Future Studies Considerations

This study is an exploratory one and therefore, is based on the literature review that exists on the issue of factors influencing the faculty decision to use educational technologies to support pedagogical strategies. The study provides a theoretical foundation and understanding of the issues facing educational institutions in implementing new educational technologies. Research methodologists appreciate the role of literature review based studies in establishing the need for further research while broadening the horizons of the researcher and preventing the researcher from conducting research that already exists (Aitchison, 1998; Khan & Law, 2015). Furthermore, literature review based studies helps the researcher and readers to be knowledgeable and understand the research problem better (Leedy, 1989). Furthermore, literature review based studies are also helpful in establishing theoretical grounds for research, identify gabs in the existing knowledge and weaknesses in previous research, discovers connections or other relations between different research results by comparing various investigations (Bless & Higson-Smith, 2000; Khan, Law, 2015). However, this is a descriptive study involving a type of document analysis and secondary research based on textual information. Some researchers question the validity and reliability of recommendations of such studies since the origin of the information needs scrutiny and critical evaluation (Khan & Law, 2015). Future studies on factors influencing the faculty decision to use educational technology to support teaching strategies should involve quantitative analysis using independent (faculty

factors), dependent (use of instructional technology) and moderating (student and institutional factors) variables as shown in Figure 3:

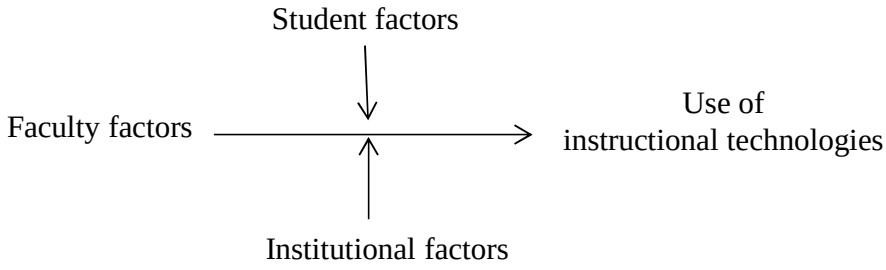

Figure 3 Factors influencing the faculty decision to use educational technologies

Abstract

This paper aims to analyze the global economic developments in recent years under the impact of economic crisis. 25 years ago, the global situation could be described as the scheme suggested by Immanuel Wallerstein: a "center" consists of small group of industrial powers, dominated by the United States, around which revolve "semi-periphery" countries with medium development, rest of the world and constituted the "periphery" massive misery in developing countries. The ascension of the emerging powers and changing their weight in the global economy also implies changes to in this picture and the balance of power globally. Emerging powers are now key decision makers of global order; the United States has to take into account. The recent financial and economic crisis, whose "replicas" continues to be felt today, brought to the fore a process without precedent internationally: moving gradual but firm, the center of gravity from developed countries to emerging economies. Over the last five years the world economy has experienced a long process of macroeconomic adjustment. The first part of the recession was recorded adjust imbalances in the private sector: reduced to a sustainable level of current account deficits in the developed and the current account surpluses of emerging and developing countries.

Keywords: global economy, European Union, financial crisis, GDP, BRIC

1. Introduction

From many ponts of view year 2008 marked the beginning of a new period in global economy. For many people this year marked the beginning of a period of crisis, called first financial, then economic and financial originally global crisis and then after a few years, a crisis of the old order, a crisis that did not affect in fact all world economies and certainly rewrote the world rankings.

Recognizing new realities of the economy and international politics, Robert Zoellick, World Bank President drew attention to the globally changes in the situation, stressing that "the world today has more poles of growth, more options in terms of growth strategies leaving to the past the unipolarity, single-leadership strategy of developing unique and unique ways.

According to some personalities of the economy, today the most relevant emerging powers group includes a total of seven countries, namely China, India, Brazil, Russia, Indonesia, Mexico and Turkey. Representative of this group (by economic and geostrategic potential) are considered China and Russia. Among them, Brazil, Russia, India and China (BRIC) are allied to major common objectives, despite the economic and socio-political peculiarities, and are platoon leaders.

12 years after they were called "locomotives of the world economy" countries that make up the group BRICS are enjoying significant economic growth, even if growth rates do not reach record levels as in prioada before the financial crisis of 2008-2009.

During the crisis, the BRIC nations - Brazil, Russia, India and China - became the engine of the global economy; China's GDP grew at 7.9%, while the United States suffered a drop in GDP. Fiscal stimulus totaled in India, Brazil and China rich the record sum of 870 bln. $. Since then, the BRIC countries have provided 85% of global economic growth. But lately, these engines have slowed amid

the 4 states desire to curb inflation using interest percentage increase, and the future policies to ensure that rapid growth does not happen again.

Rapid economic growth and increasing involvement in international trade of emerging economies, particularly the big players - such as China, India, Brazil and Russia, also known as the BRIC countries - is often perceived as a threat to the economic position of developed countries, while the shares of major players on the scene of traditional global trade have suffered significant decreases in the past decade, the most affected being the USA and Japan.

Thus, developing countries experienced in 2009 only a reduction in growth (from 5.6% in 2008 to 1.2% in 2009), but a decrease from the previous year. Some regions of the developing countries (East Asia and Pacific, South Asia) experienced in 2009 even substantial increases of 6.8% and 5.7% respectively.

It should be noted that such growth rates were not seen in developed countries, especially European Union countries, even during periods when there were no phenomena of economic crisis. In 2009 the US experienced an economic contraction of -2.5% and -3.9% in Euro area; however China has experienced an increase of about 7.5%. In turn, India has experienced in 2009 an advance of 6.6% and South Korea in 2009 had a slight growth of 0.13% (but not decrease).

Another important issue for the global economy is the shift from G7/G8 to G20, which highlights developments in emerging countries and the importance of their decisions much more enhanced. Change is a clear signal that important decisions can no longer take in a small circle. Between 22 to 23 February 2014 took place in Australia meeting of finance ministers and central bank governors of the G-20, which represents about 85% of the world economy. In the final communiqué presented after meeting states that G20 member states will develop ambitious and realistic policies that will lead the next five years the cumulative GDP increase by more than 2% above the level implied by current policies.

G20 member states have expressed regret that emerging economies do not have a higher share of voting rights in the IMF and urged the US to ratify the reforms before the next meeting of the G20. Major emerging powers such as India, China, Brazil and Russia, demanding a greater share of voting rights in the IMF to reflect their growing share of the world economy.

International Monetary Fund adopted a reform in 2010 that reinforces its share in emerging countries, but its entry in application depends on ratification in the US Congress, who has veto rights in this institution.

Even if they share the same interest for stability and openness to the West, the emerging powers, primarily the exponential, China, India and Russia, promote economic development means different from traditional powers, the US, Japan, the European Union. Faared new world order described by Zakaria - in "The rise of the rest" will include besides Turkey, Saudi Arabia, Russia, Mexico and other emerging economies, namely, Indonesia. This country will play an important role in the new global configuration, as is apparent from Alfred T. Mahan's theory that states that the XXI century will be decided in the Indian Ocean.

Increasing importance of emerging countries as export markets for developed countries reflect the increasing availability of hard currency resources of these countries, dynamic expansion of a middle class and wealthy large as increasing and diversifying their demand for imported products.
In 2013, however, the large emerging countries, China, Russia, Brazil and India have begun to face economic difficulties, reversing the high expectations of international markets. Economic stagnation, high corruption, indebtedness of the financial system and fiscal issues are some of the drawbacks countries called BRIC acronym.

Given all these problems encountered by Member BRICS the investors found a good time to seek so-called the "next big thing" in global markets. Jim O'Neill, the economist who invented and popularized BRIC name, came up with a new proposal for investors, namely MINT group, composed

of Mexico, Indonesia, Nigeria and Turkey. The four countries benefit from significant economic growth, and a young population and large, which should help them to grow rapidly when the aging trend and decrease of it will lead inexorably to slower rates of growth in many developed countries (and China) over the coming decades.

Another advantage is represented by geographic location that facilitates their chance to take advantage of large markets nearby. For example, Indonesia is close to China, Turkey, on the outskirts of the European Union and Mexico at the door of America. Geographical advantages exist for Nigeria, although less immediately obvious. The country has increased the demand for fuel and raw materials for the industry and with other countries in the group - are leaders of Mexico and Indonezia- production. Of the four countries, only Nigeria is a member of G20. However, it is now seen as the next emerging economy of Africa.

Fig 1.1. Economic indicators for MINT countries (Mexico, Indonesia, Nigeria, Turkey)

So there are authors who have already identified groups of countries with the potential to compete with Brazil, Russia and India and even the Republic of China, for example Next-11 or N-11 ("next 11" listed alphabetically: Bangladesh, Korea South, Egypt, Philippines, Indonesia, Iran, Mexico, Nigeria, Pakistan, Turkey and Vietnam), among which stands out in particular four of the 11 mentioned above: Mexico, Indonesia, South Korea and Turkey. However, BRICS alliance is the most formidable group among emerging economiesand China, Brazil, India and Russia are and will continue to be, the most powerful emerging economies of the planet.

2. The Main Centers of Power in the Global Economy

The whole history of humanity teaches us that the power balance is continually changing. International economic system since the beginning of the XXI century is a period of transition and readjustment generated major changes occurred in the early 90s, followed by the events of 11

September 2001 and the end of the world economic and financial crisis 2007-2008 whose effects are felt today.

Table 2.1: Comparison between the main centers of global power based on macroeconomic indicators for 2013

INDICATOR / COUNTRY	US	CHINA	JAPAN	EUROPEAN UNION
GDP at PPP	$ 16.720 trillion (1st place)	$ 13.390 trillion (3rd place)	$ 4.729 trillion (4th)	$ 15.850 trillion (2nd place)
nominal GDP	$ 16.720 trillion (1st place)	$ 9.330 trillion	$ 5.007 trillion	$ 16.950 trillion
GDP growth rate	1.6%	7.7%	2%	0.1%
GDP / capita	$ 52.400 (4th)	$ 9.800 (No. 121)	$ 37.100 (36th)	$ 34.500 (41st)
GDP structure by sector				
1. Agriculture 2. Industry 3. Services	1.1% 19.2% 79.4%	10.1% 45.3% 44.6%	1.1% 26.3% 72.5%	1.8% 24.7% 73.4%
Forța de muncă	155.4 million (4th)	797.6 million (1st place)	65.62 million (No. 9)	228.6 million (3rd place)
Rata șomajului	7.3% (79th)	4.1%	4.1%	10.5%

Today, we can say that the European Union, USA, Japan and a ever increasing proportion lately China are the main centers of power in the global economy. And between them occurs the main international trade.

Changes that occur in global economic have changed the power map. Looming, the world forged by Americans after World War II is coming to an end. World outline of decentralization system is clearly distinguished by long time but its new center coordinates have been far troubled and problematic. However compose the new core of a world in which change will be dynamic, uneven and unpredictable multidirectional.

China's rapid economic growth and increasing influence in relations with other countries has caused concern in Washington because the United States faces a new rival for global domination. China could exceed the purchasing power of the US economy most likely in 2014, according to World Bank estimates. This means that America will cease to be the largest producer in the world for the first time since surpassed the UK in 1876. However, analysts believe that there are important factors limiting China's potential to become a world power.

Amid the recession and the changes that followed traditional big players on the global economic scene have suffered significant decreases, but in 2013 they began to show signs of recovery. So even if recent years have been characterized by a rise of emerging countries throughout the US, Japan and the European Union have most developed economies in the world.

2.1. United States of America

USA have the largest and most technologically economy in the world, with a GDP per capita of $ 49.800, and is the largest and most diversified market for goods and services in the world, where they face daily numerous trade offers and business projects from all countries of the world.
Broadly, the American economic system can be defined by its decentralized nature, capitalism based on private ownership and free enterprise. Federal authorities that intervene in the economy are manifested through fiscal and monetary strategies. Meanwhile, the federal budget has a component aimed at investment in research. US economic legislation allows control of government involvement in business practices, having the US government and the role of supervisor of growth. In this market economy private companies make most decisions and federal authorities and central purchasing goods and services from the private sector. US private companies benefit from greater flexibility than those in Western Europe or Japan regarding the expansion of production sites, dismissal of workers, new product development. Also, US companies face greater difficulties in trying to penetrate the market rivals than they foreign firms seeking to penetrate the US market.

Services contributed with 76.7%, the most important sector of the American economy. The industry accounted for 22.2 and agriculture sector contributes 1.2%. Even if the services were the largest contributor, the United States remain a great industrial power. It notes the car industry (Ford, General Motors), aerospace (Boeing), pharmaceutical, IT (Apple, IBM, Intel, Microsoft, Yahoo, Google). Private sector activities hold 55.3% of the economy, federal institutions and the remaining 24.1% 20.6% goes to local institutions' activities.

The recession of 2008-2009 has severely affected the US economy. The financial crisis of the mortgage market with high-risk (subprime), falling prices for housing, failures of investment banks, lending restrictions and the global economic downturn have pushed the US into recession in mid 2008. GDP fell steadily until the third quarter of 2009, causing the greatest depreciation after the recession of the "30s. Since the financial and economic crisis of 2008-2009, the Fed (and other central banks of the countries affected by the crisis - ECB, Bank of Japan and others) adopted a policy of buying bonds and reducing policy interest money to supplement liquidity in the market and avoid blocking lending.

To help stabilize financial markets, in October 2008 the US Congress has allocated 700 billion dollars for the "Trouble Asset Relief Program" (TARP). The government used some of these funds to purchase shares of US banks and industrial corporations, and most of the funds have been returned by 2011. In January 2009 President Barack Obama signed a bill which approved the allocation of other 787 billion for tax incentives to be used over 10 years, two-thirds for additional expenditures, and one third for cutting taxes, creating new jobs and help the economy to recover.

In 2010 and 2011 the federal budget deficit reached 9% of GDP. In 2012 the federal government to cut spending and the deficit fell to 7.6% of GDP. The wars in Iraq and Afghanistan have increased the military department expenditure and contributed to increasing budget deficit and public debt. In 2011 the direct costs of these wars totaled about 900 billion dollars, according to US government statistics.

In March 2010 President Obama passed a law "Patient Protection and Affordable Care Act" providing for reform in the health system, and inclusion in the list of beneficiaries of health insurance to about 32 million people by 2016, and the Dodd-Frank Wall Street Reform and consumer protection Act, designed to promote financial stability by protecting consumers from abuses, and improving accountability and transparency in the banking system in particular.

In December 2012 the Federal Reserve Board (US central bank) has indicated its intention to purchase securities backed by mortgages and government bonds in an attempt to lower interest rates in the long term, and to maintain short-term interest close value 0 until the unemployment rate falls below 6.5% or inflation reaches 2.5% higher values. Sfasitul the 2013 Fed announced that it has decided to maintain interest rates at the range between 0% and 0.25% as US economic growth, which has slowed down due to "transitory factors" face risks even if global financial market tensions eased.

The main long-term problems include the American economy stagnating salaries for low-income families, the rapid growth of pension costs and health mediacală due to aging, energy supply shortages, elevated current account deficit and budget deficit.
The financial crisis has cost the US economy between 6.000 billion and $ 14.000 billion, and the damages could be more than two times higher if the economy is recovering too slowly, according to estimates of the Federal Reserve (Fed) of Dallas, quoted by Mediafax news agency. Some damage on long term to the US economy, the Federal Reserve identifies high unemployment and lost opportunities because of support for the financial sector with 12.600 billion dollars, evidenced in the central bank, published five years after the collapse of investment bank Lehman Brothers . The economic damage is equivalent to 40-90% of GDP of the US, or 50000-120000 dollars per household.

Although major financial intervention of the state in the economy prevented a collapse, aid companies were unfair and non-transparent form of transfer of the burden on taxpayers, according to the Fed.

Fig 2.2. Gross Domestic Product evolution of the United States during 2004-2013

According to statistics provided by the Bureau of Economic Analysis of the US Department of Commerce, the real growth rate of of the United States gross domestic product in 2012 was 2.2%, compared to a level of 1.8% in 2011. GDP growth 2012 was bolstered mainly: private consumption, fixed capital investments, exports and stocks from the economy. The negative impact on economic growth was produced by reducing government spending at both the federal and the states and increasing imports (imports are subtracted from the GDP calculation). The production of durable goods, work in the financial sector and insurance and wholesale trade were the main contributors to real GDP growth. Instead, the agricultural sector had a negative contribution to growth.

Fig 2.3. The evolution of unemployment in the US between 2009 and 2013

Regarding developments on the labor market, there is a relative improvement. The Ministry of Labour in January 2013 reveals that in 2012 the average monthly new jobs created amounted to 153,000, close to that of 2011. The unemployment rate decreased to 7.8% in December 2012 (8.9% in December 2011), the lowest in four years. In December, the number of unemployed remained almost unchanged at 12.2 million. Of these, 39.1% were unemployed for 37 weeks or more. The rate of employed persons, 58.6% remained also relatively unchanged.

The number of employees increased by 1.74 million in 2012 (1.64 million in 2011), the most outperform the US labor market after 2006. Although the number of employees increased employment crisis could last many years, say experts, given that jobs in administration, both at the federal and local level is decreasing. The crisis in the banking and the phenomenon of delocalisation of industrial production made an important engine for creating new jobs no longer work.

The inflation rate, measured by the consumer price index, registered a noticeable fall in 2012, standing at 1.7% in December compared to December 2011, compared with 3% recorded in 2011, according to the Bureau of Statistics Department American Labour. This marked improvement was due, for the most part, reducing energy prices (whose index increased by only 0.5%, marking a strong growth slowed from 6.6% marked in the previous year). Especially spectacular fuel prices have decreased, the price of gasoline increasing by only 1.7%, compared with increases of 13.8% recorded in 2010 and 9.9% in 2011. The energy price index declined for the population in 2012, falling by 1.1% after increasing 1.8% in 2011.

The secret of success is linked to US economic and invested huge sums in research and development by both private companies and federal authorities. Another success factor is the readiness and the number of research personnel. In the next 15-20 years, in a multipolar world, even if they hold less power than in past decades, the United States will continue to influence the evolution of the international system to a greater extent than any other global actor.

2.2. Japan

From the economic point of view Japan is between the top 3 countries in the world. Currently the Japanese economy is in a deep process of transformation caused by events such as the 2008-2009 recession and its effects. For over 30 years, Japan was the second economy in the world, but in the second quarter of 2010 was exceeded by China.

Japan is among the countries most affected by the economic and financial crisis, which caused and close relationship with the United States economy. The effects have been felt since the beginning of 2009, when Japan's exports fell by a record rate in January according to data released by the authorities in Tokyo. Official figures showed that exports fell by almost 50% in the first month of the year, while imports fell by a third. Also, these reductions have resulted in an advance-record current account deficit. Thus, the current account deficit of the Japanese economy reached in January to 172.8 billion yen ($ 1.8 billion). It was the first current account deficit recorded for Japan's economy after 13 years. These data have affected the Japanese currency, which recorded the Forex market depreciation against almost all major currencies. Japan has been hit hard by waning demand for domestic products internationally in the downturn. Most products exported Japanese cars and electronic items, recorded the biggest falls in demand. Only automobile exports fell by 66.1%, while exports of semiconductors and parts for electronic products fell by 52.8%. We can talk about a paradox in the Japanese economy by the fact that although it has a huge foreign debt, though Japan is the largest creditor in the world. Japan's net foreign assets reached in 2011-253010 billion yen (about 3.200 billion US dollars), according to the Japanese Ministry of Finance.

At the end of 2011, the world Japan's debt was 3,000 bln. And during the recent global liquidity crisis, the Japanese archipelago saved, almost alone, the International Monetary Fund itself. Japan is from 21 years in the position of largest creditor of the world. The data for 2012 confirms this position, achieved thanks to massive foreign acquisitions of Japanese companies, encouraged in this direction and state authorities.

After the 2010 IMF data, the indicator NIIP (Net International Investment Position) ranked first in the world - Japan, with 3,087,703.98 million, followed by China with only remote 1,790,651.81 million. NIIP is defined as the arithmetic difference between total foreign assets held by residents of a country, minus the total national assets held by foreign entities.

Investors take into account the NIIP indicator in assessing the creditworthiness of a country, which explains and maintaining the credibility of Japan's financial markets, despite the external debts of over 220% of GDP. Gross foreign debt of the state increased 5.5% in 2011, reaching 329.038 billion yen (about 4.200 billion US dollars), ie $ 33,000 / capita. Judging by the Maastricht European criteria which limit public debt to 60% of GDP, Japan would be in a catastrophic state debt to 229.1% of GDP.

In the historical evolution highest exposure of the Japan in foreign markets, nearly 300,000 billion yen (3.700 billion dollars) was recorded in 2009 in the midst global financial crisis was the moment when certain loans provided by Japan proved almost providential.

Japan's economy has advanced by 2% in 2012, supported mainly by robust private consumption (2.3%), government spending (2.6%) and public investment (12.6%), while net exports had a negative impact on growth (-0.9 pp). Unemployment remained at low levels of 4.3% (among the lowest among OECD countries), the experts saying that this level will be maintained over the entire forecast period.

Table 2.2. Evolution of the main economic indicators of Japan in 2009-2013

INDICATOR	2009	2010	2011	2012	2013
GDP (bln. $)	4850	5040	5500	5900	5960
GDP per capita calculated by the PPP (in $)	31,322	29,625	31,029	30,764	31,425
Inflation rate	-1.34%	-0.72%	-0.28%	-0.03%	1.61%
Unemployment rate	5.05%	5.05%	4.58%	4.35%	4.41%

Source: Table made by the author, according to data from www.tradingeconomics.com, www.inflation.eu and www.wto.org

The economic boom sustained by the 17 trillion yen (3.6% of GDP) allocated for expenditure on rebuilding the country in 2012, is at the top of government spendings OECD experts anticipating in December 2012 a drastic reduction in their coming years. Although the tax increase projected for the next 25 years and reduce expenses and taxable income will cover in part costs, costs of reconstruction emphasizes current difficult fiscal situation. The budget deficit of around 10% of GDP during 2012-2013, increased further debt.

Nippon Parliament approved at the beginning of August 2012 doubling by 2015, of the consumption tax (VAT) in order to reduce the budget deficit and ensure the social protection system. The document provides for raising VAT from 5% to 8% in April 2014 and to 10% in October 2015. The government claims that the VAT increase will generate additional annual revenues of 13.500 trillion yen (170 billion dollars). Japan's public debt was equaled in 2012-8890 billion, equivalent to 219% of GDP.

Worsening of trade balance continued in 2012, when it recorded the largest trade deficit in history, of 9,400 billion yen (about 118 billion US dollars), 170% higher than in 2011 amounted to $ 54.3 billion

even above the previous record deficit of 2.610 trillion yen reached in 1980 during the second oil crisis.

The main causes of accumulating a deficit so consistent are territorial disputes with China, sovereign debt crisis of U.E countries and boost fuel imports. Japanese export difficulties were exacerbated by the appreciation of the yen unprecedented that Japanese products more expensive and reduced the amount of income earned abroad.

The value of Japanese exports, a key driver of Japanese economic growth has declined slightly last year compared to 2011 with 0.1% (amounting to 874 billion), the second consecutive year of decline. For the first time in the history of Japan's trade balance in relations with the European Union recorded a deficit (139.7 billion yen stood at $ -1.6 billion) due to decrease by 15% of the Japanese exports. Also, Japan marked a record deficit of nearly $ 18 billion in relations with China, 10.8% amid falling exports due to territorial disputes around the islands in the East China Sea. Instead, the value of imports increased by 5.4% to 992 billion, driven by explosive growth, with 34% of the energy imports, which reached 272 billion dollars, while the majority of Japan's nuclear reactors remained shut after Fukushima accident.

One of the most important negative aspects for the Japanese economy, especially the industrial sector is the dependence on imports of raw materials and fuels, as the country has very few natural resources. Also, the agricultural sector is not very strong, but has significant subsidies and crop yield is among the best in the world. An aging population and decreasing domestic consumption also contribute negativelly.

Japanese domestic market, which vegetates for years for various reasons such as population aging and stagnating wages, is unable to sustain growth. Seeing and increasing inventories and declining profits, companies slashed investment. Victims of massive layoffs or salary reductions, the Japanese are increasingly inclined more to reduce their consumption levels, which further aggravate the economic situation.

Due to their economic strength, but also geography, a Japanese-Chinese alliance is increasingly taken into account. Many analysts raise a potential economic and strategic axis Beijing - Tokyo that would create a true economic empire and Asia would become the most important economic area in the world.

Japan can be considered a power both regional and international, because of economic, military, and educational policies. Currently, Japan is a country of which world great powers take into account, and also a state that has a voice at regional and international levels.

Although it will feel the impact of a major political shift internally and externally, by 2025, Japan will keep their major competitive role on the world stage. Reducing the number of active population and the increasing number of elderly will force authorities to be more flexible and tolerant in terms of policy on immigration and to invest in health care and social and economic restructuring will have to focus on the products incorporating high technology, which alone can ensure export. These latter measures will be imposed due to decrease the percentage of people employed in agriculture, probably below 2%, which will require additional imports to meet the demand.

2.3. European Union

European Union taken as the main structure of supranational integration is the entity closest to the equal status of the US. Basically, the EU economy is the sum of national economies that still reluctant in the face of total integration that concern and the political side, losing often competing with the US economy, Japan or China. Regarded as a whole, Europe has the capacity, technology, financial resources and population of a great power, but lacks consensus to follow this path.

Total EU economy is slightly larger than that of the US, with a nominal GDP of $ 16.58 trillion ($ 16.58 billion) and a GDP of 16.09 trillion calculated in PPP $, has a workforce 3rd level overall, after

exports and imports ranks first in the world ranking the first trading power in the world, it is the largest commercial market in the world, but income per capita is lower than in the US due to the integration of poorer states in the East. It must not forget, however, that the figures which it places on the leading places are just arithmetic totals assemblies coming from the Member States, and they make sense as long as there is a consensus among members. It also lacks emotional and idealistic commitment that the US had when they founded. Despite the efforts and strategies as was Lisbon 2010 EU fails to regain dynamism, competitiveness (diminished by oversizing considered successful economic branches that have become bad) and the position they once held in the global economy. Other problems facing the EU in recent years are: lack of effectiveness of the socio-economic model European sovereign debt crisis, relations between states and public debt to GDP and the budget deficit and GDP, both at high levels.

In late 2009 and early 2010, some eurozone countries have begun to experience difficulties in finance debt. Uncertain market conditions made the normal operations characteristic of state loans become expensive and ultimately impossible. At that time, Member States reacted quickly and introduced measures to restore confidence, meant to help finance debt countries had temporarily having trouble borrowing money on financial markets. After substantial growth in 2008-2009, the government budget deficit in the euro area average remained unchanged in 2010 and at 6.3% of GDP. In the same period, public debt continued to grow, reaching an average of 84.1% of GDP in the euro area as a whole.

The economic crisis has shown that many European countries are facing fundamental issues and trends that are unsustainable in the long term. It also made us understand better how EU economies are interdependent. After the housing crisis of 2007 and the 2008 financial crisis, Europe was faced with another big problem, namely sovereign debt crisis, which challenged the unique currency euro.
Sovereign debt is represented by bonds issued by a state in foreign currency to finance growth that country and is generally an investment more risky when it comes from a country in developing an investment safer when it comes from a developed country. Issuing government bonds stability is an important factor when assessing investment risk in sovereign debt and sovereign credit ratings help investors to measure the risk. An unfavorable change in exchange rates and an optimistic assessment of the results of projects funded make it very hard paying the debt. Creditor's only recourse is to renegotiate the terms of the loan, but can not measure the total assets of the government.

The last 5 years have been characterized by a significant increase in public debt, both in the European Union countries considered to be developing economies and in countries with developed economies. One of the causes of these increases was a failure of public policy to reform the government sector at the right time by: reducing public spending inefficient, labor productivity growth in the public sector, early treatment of problems caused by an aging population, increasing pressure on public systems pension and efficiency of state-owned companies. In 2011 the public sector in many countries much more deeply felt the coming of another crisis, while the private sector in many countries knew an exit from recession that was long overdue.

Greece, a member of the euro area was the first state which went into crisis budget deficits after 2009 recorded a deficit of 12.7% of GDP.

The news has rattled financial markets and European exchanges, Greece's budget deficit is alarmingly high given that, as a member of the eurozone, must maintain the deficit within 3% of GDP, according to the criteria of the Maastricht Treaty. Not only that, but the Greek government deficit masked a very long time, trying to keep it within the limit of 3%, which further angered authorities European Commission and the other Member States of the euro area, especially Germany.

The Greek crisis and tensions of possible state bankruptcy strongly affected the euro area, influencing developments in the euro against the US dollar, but the effects were seen on all financial and stock markets, including the emerging ones. Greece's budget crisis, which escaped the rein on public finances, is, according to economists from around the world, the first major test for the eurozone from its appearance in 1999 with the launch of the single currency.

The year 2010 meant for Greece, the maximum aggravation of the consequences of the worst recession since the Second World War, which left behind problems such as high unemployment, public debt and large budget deficits. For Greece, 2010 also meant a year of severe austerity measures necessary for effective strengthening of the tax system and reduce the budget deficit and high public debt levels. In 2010, Greece was supported in the recovery by emergency aid granted by the EU and IMF. Unlike Ireland, which initially refused foreign aid, Athens authorities have accepted international support to avoid economic collapse. The aid, granted in May 2010 totaled 110 billion euros.

However, in 2011, Greece's economic situation was far from being stable, with a negative rate of GDP growth (from -3.5 in 2010 to -6.9% in 2011) and a rate worryingly high unemployment (17.7% versus 12.6% in 2010), with devastating consequences for public finances. As a result of this, the Greek authorities have adopted a new austerity program, adjustment program medium-term fiscal 2011-2015, which brought the restructuring of state institutions and companies new taxes, cut spending by the administrative sector public.

Greece's budget deficit declined in the first five months of 2013, the country remaining on track for achieving the fiscal targets set in exchange for financial assistance. In January-May 2013, the central government's budget deficit, which excludes spending by local authorities and social assistance, fell to 980 million euros (1.30 billion dollars) from 2.3 billion euros in the period similar in 2012, according to the Ministry of Finance in Athens. Revenues decreased in the period January-May 2013 by 8% to 19.15 billion euros from 19.6 billion euros. Budget expenditures were down 11.3% to 23 billion euros from 30.5 billion euros in the first five months of 2012.

In March 2012, the unemployment rate was 22.2%. According to ELSTAT (Greek National Statistics Institute), a record number of 1.3 million Greeks were out of work in March, while 3.3 million were registered as employed. Unemployment in Greece nearly tripled from the beginning of the crisis in 2009, and remains the highest in the eurozone, where the average unemployment rate was 12.2% in April 2012. The unemployment rate, 58.4% is recorded among young people (aged between 15 and 24 years).

Despite two support programs involving the European Union, European Central Bank, International Monetary Fund and private creditors, Greece has made 2013 the sixth year of recession, and hopes to get a respite of two years, 2016 in order to reduce the budget deficit below 3% of GDP from 10.9% of GDP at the end of 2011. In the updated fiscal plan for the period 2013-2016 Athens authorities expect a primary surplus of 3 2% in 2016 versus 4.5% previously announced.

Problems caused by high budget deficit had other countries like Portugal, Ireland and Spain. These difficulties have been caused by years of too low interest rates that led to overheating and accelerating inflation. Unlike other European countries overwhelmed by financial problems, Ireland is one exemplary story. In 2012 it managed to avoid the recession that took hold of the eurozone. Labor costs dropped heavily, making the country more competitive. Ireland's image has improved in the eyes of foreign companies, and process using low taxes.

According to the Dutch Ministry of Labour, Richard Bruton, Ireland has achieved all financial targets set, and this occurred even in an economic context underperforming, and is about to end its dependence on the International Monetary Fund and the European Union for support public finance. However, there is no certainty that it will be a happy end. Ireland's dependence on foreign firms creates economic and fiscal vulnerabilities. Thus, if the global economy will have a bad year, Ireland will be hit hard, given that exports exceed its economy.

On the opposite side of these countries with negative developments is that the Polish economy can be seen as a miracle. Poland is the only EU country that managed to avoid the recession. Moreover, she had a growth that reached in 2011, to 3.9 percent. Warsaw authorities have obtained, at the height of the crisis, a loan of 30 billion dollars from the IMF. But the Poles have not touched one dollar of the loan, which was used as a safety belt. Polish companies were encouraged to keep their positions

on the domestic market, and this market of over 40 million consumers, failed to provide stability Polish companies resources they have done outperform their contestants in the region.

Another radical measure was taken by the government in Warsaw to increase absorption. Thus, the Polish government preferred to settle the European project from its own funds and then recover the money from the European Commission. This happened not only to public institutions or administrative entities, but also to private companies. Thus, the government in Warsaw has advanced payments totaling seven billion euros in European projects account. Of these, 800 million have reached the managers of private companies that have been so encouraged to carry out the projects and write new ones. Thus, while the whole of Europe is facing a crisis of working capital, funds paid by the Polish Government have provided the resources necessary for the country's economy.

The biggest EU economy and the country that has contributed the most to helping countries with problems caused by the crisis is Germany. Once for two consecutive years (2010 and 2011) Germany has maintained a high rate of economic growth in 2012, due to deteriorating of global economic climate and the interaction of external factors by nature disruptive - deep recession manifested among countries on the periphery southern Union (EU), in conjunction with the slowdown seen in the growth rate of emerging markets and the increasing uncertainty related to the sovereign debt crisis in the euro zone - economic growth has been below potential, marking "tempering" the momentum of the German economy. According to assessments of international experts, despite restoring economic context externally started from the second quarter of 2013 with a stimulating effect on the export business, coupled with strong fundamentals underlying the German economy - a high degree of competitiveness and market robust labor - reduced performance recorded in the first months can not be offset during the current year, which resulted adjustment "shrinking" of initial forecasts. However, Germany will continue to be "economic engine and stability anchor" of the Union, and for 2014 the forecast highlights a number of favorable conditions that will generate a positive impact on the overall activity of the German economy.

In full agreement, national and international economic experts opines that another factor with negative impact on the evolution of Germany GDP in 2012 was the major reduction in the pace of domestic demand for goods and services (0.2% versus 2.2 % in 2011), under the influence of a mixed set of unfavorable phenomena, which acted both on its consumer component, especially on the investment.

As a result of the intensification of the sovereign debt crisis in the Eurozone and therefore of increasing uncertainty, there has been a relative deterioration in the index of trust in the national economic environment, generating secure behavior among consumers and a slight increase savings rate. As a result, private consumption slowed to 0.6% (compared to 1.7% in 2011), but the elements of domestic demand, has held the largest contribution to national economic growth in 2012. Among the factors behind the appreciation of real incomes and created the prerequisites for maintaining a high level of household consumption expenditures include: stabilization of the labor market and wage conditions imposed to mitigate inflationary pressures and a low interest rate monetary policy.

As shown in data recently published by the Federal Ministry of Economics and Technology, while maintaining a slow pace of economic growth, respectively, of domestic demand reduced overall euro zone but also emerging countries, development of foreign trade of Germany "engine" of traditional economic development of the country was unfavorable in 2012. Thus, amid the uncertain global economy in 2012, the volume of German exports of goods and services has fallen by only 3.7% pace (compared with 7.8% growth rate achieved marked in 2011) though as they value volume increased to about 1363 billion euro (against 1,300 billion in 2011).

Also, given the weak domestic demand coupled with diminishing German industrial production, very heavily dependent on import, the import volume of goods and services showed a major reduction rate (1.8% compared with 7.4% in 2011), marking, however, a volume value of 1211 billion (compared to about 1170 billion euros in 2011). However, exports of goods and services contributed 51.1% to the national GDP structure, while imports held a share of 45.8%, which gives Germany one of the

highest degrees of openness global economic hierarchy and the highest in the member countries of the G-7 (97.3% against 95.3 in 2011).

According to preliminary estimates prepared by the World Trade Organization (WTO) in 2012, Germany has retained third place in the hierarchy of world exporters of goods (after China and the US), accounting for 7.7% of world exports, and the export of commercial services, Germany has placed also ranked third among the world (after the US and UK), accounting for 5.9% of world trade. Regarding the structure of exports, within them, in 2012, were predominant manufacturing products with high added value: automobiles and parts for motor vehicles (17.3%), industrial machinery (14.9%), chemicals (9.5%), computers and electronic and optical equipment (7.8%).

Regarding importation of goods, the report by the WTO show that Germany maintained the third position worldwide importer (after the USA and China, accounting for 6.3% of world total), and in the hierarchy of the main importers of services trade ranked second behind the US with a share of 6.9% of the world total. As for exports, the main trade partner countries for imports were Euro Zone countries (supply of about 37.6% of imports federal) and extra-community among countries with the most significant share in imports of German goods and services include China (8.5%), USA (5.6%) and Russian Federation (4.7%).

The euro area economy emerged from the longest recession mainly due to rises in Germany and France, amid the first prolonged period of quiet on financial markets since the outbreak of the sovereign debt crisis. In the first three months of 2013, euro zone GDP fell by 0.3% compared to the last quarter of 2012. Compared to the first quarter, the strongest increases in GDP in the EU were registered in Germany, Czech Republic, Finland (0.7% each), Lithuania and the UK (0.6%), opposite hovering Cyprus (-1.4%), Italy and the Netherlands (-0.2%). Quarterly comparable data are not available for many countries, including Greece. Thus, in the second quarter compared to the corresponding period in 2012, the EU countries with the most robust rates of economic growth are Latvia (4.3%), Lithuania (4.1%), Estonia and the United Kingdom (1.4% each) and Romania with 1.2%. Romania ranks among the five largest growths in EU countries. It recorded a growth of 0.3% in the second quarter versus the first three months of the year, GDP rising by 1.2% on the same period last year. The steepest contractions were recorded in Cyprus (-5.2%), Greece (-4.6%), Italy and Portugal (2% each).

The eurozone emerged from recession in the second quarter of 2013 with growth of 0.3% over the first three months of the year, after a period of a year and a half of economic contraction, the longest of the single currency.

Table 2.3. Economic indicators for the European Union (28 countries)

INDICATOR	2009	2010	2011	2012	2013

Amid a gap that separates largely horizon of expectations of the Brussels institutions of the popular vote, in other words, the complexity of a bureaucracy increasingly loaded with its efficiency, it is expected the European Union to see his slow ascent to that level cohesion and political integration, economic and military might to impose their interests on the international arena and ideals. It remains to be seen to what extent officials plans will become a reality.

3. Conclusion

At the moment we can say that we live in a multipolar world, but we do not know if it will be strictly based on power relationships or, conversely, if you talk about a multilateral world in which all countries are subject to rules and cooperate international institutions. The US is still the largest economy globally, but emerging BRIC group of countries, gaining economic power, which is a very clear trend. Economic and financial crisis has accentuated this trend, and of onset in 2008-2009 BRIC countries were "locomotives of the world economy" save the planet from a deep recession.

Globalization phenomenon of economic, social and political inevitably leads to the creation of prerequisites and circumstances of progress and economic development, and the reconfiguration of the international economic order. In this process, an important role is played by emerging powers and particularly the BRIC group - the four economies, taken together, represent a tremendous economic force, with a diversified and highly dynamic potential, if we refer to recent years.

Currently the emerging powers are offering new models of economic growth, each bringing some contribution to the formation of a multipolar system and creates a greater diversity premise rise of emerging economies, which may BRICS development model.

For the moment the US dollar remains the most important currency, but this rule will decrease in the future. Its closest competitor is the euro if the eurozone will be able to successfully resolve the sovereign debt crisis. BRICS countries want to end the domination of the dollar in the future by creating a joint development bank and an own coins.

The US economy was severely affected by the economic and financial crisis, and even now does not give clear signs of recovery. Even if in 2013 the developed economies began to record higher growth amid problems faced by emerging countries, however, its forecast for economic growth in 2014, the IMF stressed that the American economy is affected by budget cuts significant, likely to degrade.

So far, Europe has relied on its role of soft power, the ability to achieve international objectives without resorting to brute economic force. But the sovereign debt crisis still threatens the euro area, and therefore unity and alliance zone leaders must come up with a plan of coordinated fiscal and monetary measures that reatabilească economic balance.

Considered by some experts eternal rival, China and Japan are actually co-pilots of East Asian economy. Japan was not just wealth generator in Asia, triggering domino economic boom in the region, but was and is one of the most active international powers. Economic fatigue currently facing Japan have regressed force, placing it third in the international economies.

China is a power pole steadily increasing over the past 30 years, from sixth position in 2001, surpassed the all France in 2005, Britain in 2006, Germany in 2007 and Japan in 2010, becoming the second largest economy world and now threatens the supremacy of the United States. This ascent is without precedent and managed to amaze everyone. Economic analysts are competing in making predictions about when China will become the biggest economic power in the world. Even if the Asian giant slowed GDP growth in 2013, officials in Beijing did not give assurances that the state is facing economic problems, and this relaxation period will not affect their grand plans.

Abstract

Recently, the emergence of advanced technology has impacted on all aspects of our lives; it has had both positive and negative consequences. As can be seen currently, the evolving technology can have a strong impact on people's lives, and especially if they are teenagers, as they are vulnerable to change, and it can affect them in different ways. Since they can be exposed to different types of victimization online, much research has been done in this area in order to find out about behavioural internet usage among teenagers. This study aims to explore to what extent the internet can affect the behaviour of Omani teenagers (e.g. through harassment, sensual and inappropriate content, racist/violent material), to discover the reasons why Omani teenagers engage in these negative online activities and to recommend strategies designed to minimize participation in these activities amongst teenagers. The data was collected from school students in the Sultanate of Oman, the sample size being 500 students of both genders. The research was designed to aid in the understanding of this phenomenon of bad effects produced on the youth through certain online activities and the high-risk consequences on their behaviour, and to stress the importance of minimizing these affects. The research gaps in this area include the status of teenagers in Oman and the influence of the internet on their behaviour**.** The paper concludes by highlighting the main negative online behaviours among teenagers, discussing the results of engaging Omani teenagers in such behaviours and commenting on some effective solutions for curbing these high risk behaviours.

Keywords: Teenagers, Internet, Online behaviour, negative behaviour, Oman

1. Introduction

There are several effects of globalization behaviour, and one of these is the impact that the internet, has had, and especially on teenage behaviour. The widespread use of the internet is the cause of high online risks which can lead to the teenagers victimization [Mitchell et al., 2007]. Recently, researchers have found that online victimization is associated with adult-content abuse, interpersonal abuse, bullying and many other misuses. As the number of young people online increases, the risk in them becoming involved in unsavoury activities does likewise, so that an appropriate and safe internet usage should be determined for them. A recent study shows that about 97% of teenagers aged between 12 and 18 years old are using the internet [Madden et al., 2013]. This growth in teenage internet use is leading to an ever-increasing risk in engaging online. Thus, understanding negative and risky internet behaviour is a very important step [Mitchell et al., 2011].

There are now in Oman great effort to solve such problems, raise awareness, and propose solutions to reduce the risks, and discuss ways in which to build human capacity to protect children/teenagers while using the internet. The Information Technology Authority (ITA), through the National Center for Computer Security (NCCS), has implemented several initiatives in the field of protecting children/teenagers on the internet. They aim to provide a safe internet environment for children/teenagers along with all other members of society [Observer, 2013].

In our research we discuss the effects of the internet on teenagers' behaviour, the negative online practice of many teenagers and how to minimize teenagers' risky internet usage. The study will focus on the

behaviour aspects since this is the most sensitive aspect in the Omani society. The data gathered through a questionnaire distributed among school students was to obtain their opinions, knowledge and recommendations in addition to eliciting their actual online experience.

The rest of the paper is structured as follows: Section 2 sums up the related literature on how the internet affects teenagers and, specifically, how it affects their behaviour, discussing some potential reasons for young people engaging in such activities and how to reduce the risks that this poses for their ethical behaviour. Section 3 describes the research methodology adopted in this study, followed by Section 4: Findings and data analysis. Section 5 analyses and discusses the teenagers' online usage results and the paper ends with the conclusion and limitations in Section 6.

2. Literature Review and Related Research

The use of the internet is increasing annually. The majority of people log in from their houses, followed by their work places, schools and net cafes [Ho et al., 2012]. These facts identify how the internet is becoming the most important tool in people's lives. Most facts about teenagers' behaviour online highlight the very real dangers of exchanging adult-content, experiencing harassment and bullying, and engaging in undesirable relationships with other genders , all of which will surely affect vulnerable teenagers [Martin, 2010].

What is important is that the risk expands to the teenagers themselves, as they spend increasingly long hours on-line, sending emails, using social media, downloading music, videos and games, shopping, and many other activities [Martin, 2010]. Being online for all these activities affects their performance, social life and their health as well. A study conducted in the US in 2013 revealed critical facts about teenage internet usage. It found that 95% of teenagers go online. About 74% between the ages of 12 and 17 access the internet from smart phones as well as other mobile devices. Internet usage has increased among people due to its mobile connection. Negative internet could be anything from theft, information damage, copyright infractions, digital privacy, intellectual property, and distribution of illegal content, anti-competitive attacks, disinformation, and various forms of fraud. According to the FBI; "Cyber terrorism is a form of computer-related crime committed using internet technology" [Singh and Siddiqui, 2011]. With reference to this issue, we present the following hypothesis:
H1*: Online activities can negatively influence a teenager's academic performance, social life and their health as well.*

2.1 The extent to which the internet affects the behaviour of young people

As the electronic environment changes, protective adaption changes equally. Thus, as young people shift from chat rooms to Facebook, the internet platform provides new controls and security [Jones et al., 2012]. Online activity exposes young people to many criminal, unethical activities including dealing with sensual content and the use of others' identities [Dowell et al., 2009]. With reference to this issue, we present the following hypothesis:
H2: *Online activity exposes young people to many criminal, unethical activities including sexual content and the use of others' identities [Dowell et al., 2009]*.

More important, it might also lead to Internet addiction that, in turn, will change the developing brain structure of teenagers, leading to poor academic achievements, involvement in dangerous activities, unhealthily nutritional habits, poor personal relationships and self-injurious activities [Kuss et al., 2013]. The following four categories classify the online negative activities that can influence adolescents [Livingstone and Haddon, 2008] :

1) *Content risks, including*: being confronted with sensual/violent/racist/hate material, pornography, challenging content (e.g. suicide, anorexia, drugs, etc.). Many teenagers pointed out that they search

for inappropriate content, talk about sensitive topics, read about and see internet postings on these issues [Livingstone and Haddon, 2008].

The violence is not limited to a single group, religion, culture, or background. Many teenagers create groups to discover more about other people's beliefs, religions and behaviours [Dowell et al., 2009]. This in turn might expose them to racial issues. Researchers suggest that clinical assessments on young people should include questions about online content regarding suicide situations. Also, the internet might affect them when they search for harmful content as they will be exposed to violent images and content, and there is a danger that they will act on what they have seen. Internet addiction increases the risk of self-harm, depression and suicide. Encouraging suicide online is a criminal offence. The harm extends to the use of drugs too, and researchers have found that young people use instant messaging to discuss drug issues [Barratt, 2012].

Sometimes risky internet behaviour can expose users to pornography, which is pictures of undressed people or people in sensitive postures, without seeking or expecting such pictures, when they are searching online, opening websites or pop-up links [Mitchell et al., 2007]. Some teenagers can become involved in online harassment by sending unethical photos of people to others without their knowledge [Jonsson et al., 2014].

2) *Contact risks*: *including* contact with foreigners, cyber-bullying, online harassment, etc. The internet provides teenagers with much information, but it can also expose them to greater risks and dangers. They can face dangerous people online, a variety of sensitive material, and they could become victims of harassment and bullying [Mitchell et al., 2007]. Online harassment is attacking or offensive online content that is inflicted on teenagers and seen by others [Mitchell et al., 2007]. Nearly a third, (29.5%) of the boys and 27.8% of the girls reported that they had posted rude comments online [Dowell et al., 2009]. Other types of harassment carried out by teenagers are embarrassing others by making jokes, and harassing foreigners.

Online harassment (playing jokes, making rude comments, intentionally embarrassing someone online, or bullying) are all types of bad activity conducted by teenage students that can present a really serious risk to teenagers.

The phenomenon of cyber-bulling is what researchers look for, as it is not an individual problem but involves the whole society [Thorsten Quandt, 2012]. Cyber-bullying is defined as intentional aggression used through the internet or any electronic media to harm others [Morrow and Downey, 2013]. Cyber-bullying is carried out by teenagers to make them feel more powerful by strengthening their own social position and minimizing that of their opponents in the discussion group [Festl and Quandt, 2013].
Involvement in cyber-bullying via the internet can be carried out anonymously by teenagers. It can take many forms such as flaming, harassment, cyber-stalking, denigration, imitation, exclusion, and trickery [K. Alex Burton1 et al., 2013]. The male students are more likely to be bullying others. Many teenagers said that they feel angry, unhappy, and depressed after being bullied online [Mishna et al., 2010].

H3: *Cyber-bullying is practiced by teenagers to make them feel more powerful or to strengthen their own social position [Festl and Quandt, 2013]*.

3) *Commercial risks*: advertising/commercial misuse, illegal downloading, gambling, etc.. Transferring music from the internet into users' computers is unauthorized for copyright reasons and researchers consider illegal music downloading online to be theft [Jambon and Smetana, 2012].

4) *Privacy risks*: giving/posting personal information, attacks on privacy, and hacking. Many young students post their personal information, especially onto social media websites. Research shows that 31% of boys and 27% of girls admitted that they had done so [Livingstone and Haddon, 2008]. The posting of personal information and personal pictures can lead to many risks such as harassment, cyber-bullying, privacy attack and unwanted sensual solicitations [Livingstone and

Haddon, 2008]. According to the FBI, "cyber terrorism" could be any means of threatening others. Another form is hacking. Nowadays hackers are able to penetrate even fairly well-protected systems, which poses a great threat to the security of individuals and nations alike, and increases the risk to young people and children [Singh and Siddiqui, 2011]. Identity theft: this is an easy and anonymous way to carry out illegal acts without being exposed to any risk of getting caught [Singh and Siddiqui, 2011].

Thus, a fourth hypothesis is presented as follows: H4: *Omani teenagers can be impacted by many negative activities.*

2.2 The involvement of teenagers in negative behaviours on the internet

Young people are connected with others through the use of the internet and other media devices. These media become the tools for practising bullying behaviour [Huang and Chou, 2010]. The rise of teenagers going online via smartphone (mobile devices) Wi-Fi connections seems to pose the potential problem of internet misuse [Kuss et al., 2013]. Teenagers who post their personal information or pictures, involve themselves in inappropriate behaviours and have contact with strangers are most likely to be at risk [Sengupta and Chaudhuri, 2011]. There are many factors pushing teenagers to become involved in negative behaviour on the Internet. Nowadays social networking websites are considered to be one of the main sources of teenage harassment online [Sengupta and Chaudhuri, 2011].
The anonymity factor plays a role in increasing such negative internet behaviour, as young people can hide themselves behind screens to carry out bullying acts and, in turn, the bullied victims will then take revenge in cyberspace [Huang and Chou, 2010]. When teenagers were asked about why they hurt others, they replied that it was because it was made possible by the anonymity of the space.

The internet tis a tool might be misused by teenagers themselves as it give them the ability to broadcast illegal products such as drugs, either directly via social networking sites and online auctions or indirectly through pop-ups, to catch teens [Forsyth, 2012]. Moreover, teenagers who have the material resources and the knowledge of how to use the internet are more likely to engage in such negative behaviour [Moule Jr et al., 2013]. The life style that the teenagers live affects their internet behaviour, which may lead to a greater likelihood of their exposure to online pornography [Moule Jr et al., 2013]. Teenagers who participate in street crime have a greater chance of practising negative behaviour online, in their use of the internet in dealing with others [Moule Jr et al., 2013], and teenagers who harass others at school are more likely to be perpetrators of cyber-bullying [Mishna et al., 2012]. The widespread use of advanced technology gives teenagers the chance to access pornography [Miller, 2013].

Studies found that teenagers with married parents are less likely to be online, while it is more common for teenagers with divorced parents. The reason appears to be that they have greater unsupervised internet access and therefore face higher risks such as contact with strangers and people looking for unwelcome social relationships [Sengupta and Chaudhuri, 2011]. When teenagers use the internet secretly, away from parents' attention, there is a 60% increase in the likelihood of their being cyber-bullied [Sengupta and Chaudhuri, 2011]. With reference to this issue, we present the following hypothesis:
H5*: Omani teenagers with married parents are less likely to be bullied, while it is more likely for teenagers with divorced parents.*

From the teenager's perspective, a common reason for becoming involved in negative online behaviour is to humiliate friends, and spending a long time on the internet in their free time can exacerbate this behaviour [Mishna et al., 2012]. The availability of time in a teenager's life increases the risk of their using the internet negatively. Another reason for going online was found to be the sharing of feelings because that they had never disclosed offline. Many parents are not aware of the likely effects the internet can have on their children [Álvarez et al., 2013]. Even the teenagers themselves may not be aware of the risks posed by internet utilization. Regarding online harassment, bullied victims reported that they felt sad, nervous, afraid and unable to focus at school, and that it had exposed them to social difficulties. They might have been encouraged to use drugs and alcohol, play truant from school, procure eating disorders,

and take weapons to school [Mishna et al., 2012]. With reference to this issue, we present the following hypothesis:
H6: *Many parents are not aware of the risks that their children are exposed to through using the internet [Álvarez et al., 2013]*.

Experiencing feelings of anxiety and depression can lead to more negative behaviour [Hedman et al., 2013], while teenagers who cyber-bully might engage in rule-breaking and have problems with aggression [Mishna et al., 2012]. Studies found that when young people use the internet intensively in private they are much more likely to misuse it [Mishna et al., 2012]. Often young people misuse the internet because they have been rejected by friends and have adjustment problems [Mishna et al., 2012]. Also, perhaps they have experienced violence or harassment by school staff [Mishna et al., 2012].

2.3 How to control the negative online behaviour among young people

Young people's usage of the internet has caused concern for both educators and the media [Jones et al., 2012]. There are calls for restrictions on internet use by teenagers [Sengupta and Chaudhuri, 2011], and setting rules and regulations for computer use by teenagers will restrict its usage [Robinson et al., 2010], and that monitoring teenagers' computer use will lead to a reduction in their exposure to inappropriate internet behaviour [Sengupta and Chaudhuri, 2011].

Many responses have indicated that to filter and/or block illegal and unethical sites will be the best solution for protecting today's youth [Robinson et al., 2010]. Some of the content, and especially that of social networking sites, needs to be monitored and corrected regarding its unstructured and unsupervised peer content [Geeraerts, 2012], and parents have an important role to play in minimizing the risk the internet can present to their teenagers. Drawing up regulations for internet use in the home, being responsible about the amount of time spent online, selecting the appropriate location of the computer and monitoring the content accessed could go a long way towards minimizing these risks [Álvarez et al., 2013].

Parents also have a role in raising their children's awareness about the dangers of giving personal information to strangers online and the sites that they should not visit, and staying close to them in order to monitor their doings [Álvarez et al., 2013]. They can monitor their search history in the browser software [Robinson et al., 2010]. Parents also should give advice to their children about internet safety and responsibility. Whereas many teenagers can access the internet anytime and anywhere, this connection needs to be monitored and controlled as well [Kuss et al., 2013]. The authorities should use their power to prosecute the people who misuse the internet to harm teenagers. About 70% of the latter said that they did receive advice from a teacher or other adults in their schools about appropriate internet usage. With reference to this issue, we present the following hypothesis:
H7: *The society can play a role in reducing the negative effect of internet usage.*

2.4 Internet usage in Oman

Oman possesses technology development due to investment in the telecommunication industry [Oman - Telecoms, 2013]. Statistics show a rapid increase in internet usage in Arab countries: they now count for about 3.7 percent of world users. The total number of Arab internet users is 90,000,455 according to Internet World Stats.

Last year Omani internet users reached 2,101,302 users. According to the World Bank, in 2012-2013[EAST, 2013] there were 60 users in Oman per 100 people [Oman - Telecoms, 2013]. About 68% of the population is now using the internet in the Sultanate of Oman. Statistics that only focus on social media sites separately show us that 120,840 Omanis use Facebook, while 6550 use Twitter and 169,000 use LinkedIn.

3. Research Methodology

In our research a questionnaire was chosen as the data collection instrument. The questionnaire was prepared, then printed and distributed among school students. The sample size of this study was 500 students.
The school students had to fulfil the following criteria to be included in the sample:

- Be over 12 years old (either male or female)
- Have access to a computer, smartphone or any other device to go online
- Have access to the internet
- Be able to participate in the study

The questionnaire was designed to elicit the valid opinions and views from students, avoiding bias. It was decided to use this instrument to reach as many respondents as possible, to offer them anonymity, and give the students enough time to respond easily. The questionnaire was distributed amongst the Omani students was in Arabic language and contained open-ended and closed questions.

4. Findings and Data Analysis

4.1. The extent to which the internet affects young people's behaviour

The size of the sample was 500 students; comprising about 50% male and 50% female students aged between 12 and 18 years old. The study showed that just 5% of the students went online from 1 to 3 hours daily, 25% used the internet for 3 to 5 hours, about 50 % stayed connected for 5 to 7 hours, and 20% were online for more than 7 hours a day, as is shown in Figure 1 below.

82.5% of the students think that going online affects their academic performance, social life and their health as well, whereas 17.5% of them think it does not. Therefore, hypothesis [H1] which assumed that *'online activities can negatively influence teenagers' academic performance, social life and their health'* is accepted.

Hypothesis [H4] '*Omani teenagers can be impacted by many negative activities'* is also accepted. There are many negative online activities experienced by students; illegal downloading (music, programs or other content) was at the top of these activities (85% of the students admitted to doing this). While searching for inappropriate content and forming relationships with strangers came second with a percentage of 82.5%. About 55.5% of the students admitted that they used adult-content exchange, while 36% of the students had used hacking and 25% confessed that they had harassed others online (see Figure 2). Therefore hypothesis [2] that assumed'-*online activity exposes young people to many criminal, unethical activities including dealing with sexual content and using other people's identity*- was accepted.

There are a significant number of findings which illustrate that 70% of the students have harassed others online, for enjoyment and a feeling of power, while just 30% have not. This confirms the hypothesis [H3] that *cyber-bullying is practiced by teenagers for enjoyment and to give them a feeling of power, strengthening their own social position.* However, the conception of the majority of students about the engagement of young Omanis in negative online activities is that social media is one of the main 'enablers' of negative online activities amongst the youth, free time, feel bored, it being seen as a negative social-influence, and lack of entertainment activities or clubs to spend their time.

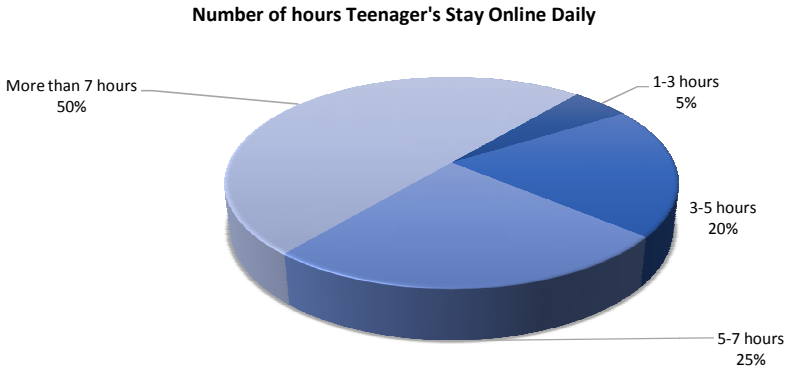

Figure (1): Number of hours students stay online daily.

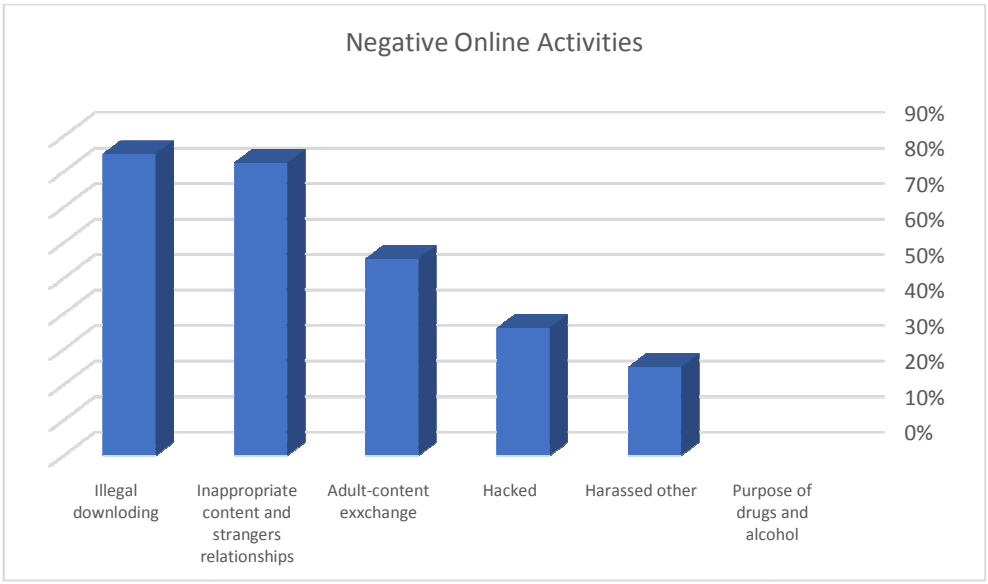

Figure 2: The study results concerning the practice of negative online activities

4.2. The involvement of teenagers in negative internet behaviour

Regarding whether the parents specify and monitor time for their children to be online or not, 88.5 % of the students said 'no' (these students have 87.5% of their parents married). However, only 11.5% of them said 'yes'. Concerning the recommendations of the students on how to minimize the involvement of children in negative activities while they are online, most of them recommended blocking inappropriate websites, while many of them recommended that teenagers spent their online time engaging in educational activities and clubs rather than being online just for chatting, although some of them suggested that parents should monitor their children's internet usage and control the length of time they spent online. From these results it can be observed that the hypothesis [H5] that *Omani teenagers with married parents are less likely to be bullied, while this happens more frequently to teenagers with divorced parents*- was rejected. However, the hypothesis [H6] that *many parents are not aware of the risks that the internet might pose on their children* was accepted.

4.3. Controlling negative online behaviour among Omani youth

One question was about the role of society (citizens, law enforcement, schools, and parents) in minimizing negative internet activities that influence teenage behaviour. All the students agreed that there were three main actions to be taken in order to minimize the effect of the internet on their behaviour: schools should give them lectures to make them aware of the consequence of misusing the internet, point out the serious risks that might affect their behaviour, and teach them how to use the internet appropriately. Approximately 70% of the students indicated that parents should warn their children about online risk activities and monitor them. Concerning law enforcement, they proposed setting up laws to restrict internet access and prevent users from misusing the internet. It is notable that the hypothesis [H7] that *society can play a role in reducing the negative effects of internet usage* was accepted.

5. Discussion

As the findings show, the answers explore many hidden areas in teenager's online usage. Concerning internet access, the results vary considerably among Omani youth. The majority of the teenagers admitted that they use the internet for 5 to 7 hours a day, while many of them use it for 3 to 5 hours and some of them are on it for more than 7 hours. Actually, the negative online behaviour is not limited to those who are connected for long hours. Almost all of them have harassed others. Of the teenagers who said that they harassed others online, more than half were boys. As mentioned above, there was no obvious relationship between hours spent online and the practice of negative online activities. Intentionally or unintentionally, more than half the teenagers downloaded content from the internet illegally, and as downloading music is considered to be stealing copyrights and is a crime by law, it would appear that many of them do not pay much attention to their infringement (Singh and Siddiqui, 2010). The surveyed Omani students believed that the most serious negative online behaviour is using the internet for the purpose of buying and selling drugs and alcohol among teenagers, and this is because it is not just a form of electronic harm but extends to the encouragement of serious illegal practices. The accessibility of social networking sites facilitates considerably discussions about drugs among youth [Barratt, 2012].

The second highest online negative risky activity was communicating with strangers. As the danger of contacting with foreigners worries parents more because of giving personal information from young people, thus facilitate foreigners attack [Geeraerts, 2012]. The pornography search rose among both male and female, this is why all of the students report blocking the illegal and pornography sites as one solution to reduce the negative online behaviours among young people. It got the highest frequency reported solutions to solve this problem.

Hacking is practiced more by boys than girls, who like to explore and discover new things, helped by the availability of advanced software that facilitates hacking and the breaching of other people's computers.
The exchange of sexual material also rose among both males and females, but is more frequent among boys than girls. Here again all of the students agreed that pornography sites should be blocked to get rid of such online misuse, and that internet usage should be monitored by the parents [Sengupta and Chaudhuri, 2011]. Many of the students reported that such content appears in pop-ups or links that lead to these unethical photos or videos [Mitchell et al., 2007].

After that, the online harassment reported by boys more than girls. Many of them figure out that they did harass others. As studies show, the harassers increase by boys more than girls [Mishna et al., 2010].

Most of the students know about the risks and sequences of engaging in negative online behaviour, and they provide valued recommendations to solve this phenomenon. To begin with, they report convincing causes that lead young people to misuse the internet. The high frequency reported reason was the feeling bored and having free time [Mishna et al., 2012]. The lack of entertainment activities for youth and sports clubs make them feeling bored so much they switch to spending their time on the internet, which increases the probability of using it negatively [Mishna et al., 2012; Robinson et al., 2010]. The negative social influence was the second highest reported reason for teenagers engaging in such negative attitude.

The availability of internet access and resources like money or devices increase the likelihood of being exposed to unwanted material.

The lack of parent monitoring and internet security obviously has a great influence on youth online behaviour. There should be strong security that limits their internet access and connection as well as monitoring by parents and advice to raise awareness about using the internet and dealing with any online risks that may face them [Álvarez et al., 2013]; [Robinson et al., 2010]. Many students report a lack of awareness of the dangers of utilizing the internet and the consequences of engaging in bad online behaviour. In Oman, there should be comprehensive cooperation to raise awareness among young people about correct internet use.

Also, there are laws and regulations set by the Information Technology Authority (ITA) which assign great importance to the security of children on the internet in Oman. They collaborate with the regional and international organizations in this field.
They set laws against electronic crimes, doubling penalties in cases where the targeted victims are children. Also, a National Centre for Computer Security Authority has been established to protect young people online, educate children, teachers and parents in the means of protection to avoid young people presenting a security risk.

6. Conclusion

This study provides a better understanding of the impact of the internet on Omani teenager's behaviour. Since little research has been done in this area, this research will give Omanis a clear picture of the risks and impact associated with the use of the internet by teenagers. The results show that many teenagers download internet content without being aware that it is illegal, harass others, hack other people's computers, and search for sexual content online, and all these activates will affect their lives in a negative way. Thus, educators, law enforcement, parents, local clubs and the government should play an effective role in providing sufficient information for young people in the use of the internet and warn them about the bad effects of using it indiscriminately.

Abstract:

There is a lack of awareness towards managing and protecting digital data in the Land Registration System (LRS) under the Ministry of XYZ. The data which has been carelessly managed can be classified as a very important data in Malaysia since cover all concerning. It so forth the data about land in Malaysia, like the name of land owner, land size, type of land and others. All these data had been stored in one server called LRS Database Server which functions like a data warehouse for each land district in Malaysia. However, the digital data security control that being implemented for the system is not fully execute, as a result the volatile information is exposed to irresponsible people. This study focuses on the security awareness and it implementation towards Land Registration System (LRS) data warehouse in land district office and as well as land state office in PQR. . In addition, this study identified the weak point of security at the data warehouse. Therefore, recommended solutions to solve the problem are stated.

Keywords: *Data, Security, Information Security, Computer Security*

Introduction

The Land Registration System (LRS) project was developed by ABC Sdn. Bhd. under Director General Department of Land and Mines (DGDLM) supervision. LRS has been proclaimed as a successful project because of its effectiveness and efficiency which every district and state users use the system in their daily work effectively. Furthermore, it is the first computerised land system in the country and it has improved the time taken in completing tasks such as data storage and retrieval as compare to the manual system before.

The hardware that is being used to store the LRS database server was supplied by SUN with SOLARIS operating system. ORACLE 12 is being use as their database. It is a high-end storage server and capable of running 24 hours per day continuously (DGDLM, 2008).

Even though the LRS can be categorised as the most crucial system in Malaysia during the days, but there is lack of awareness towards managing and protecting information in the LRS data under the Ministry of XYZ. The data which has been carelessly managed can be classified as a very important data in the country since cover all concerning (DGDLM, 2007). It so forth the data about land in the country, like the name of land owner, land size, type of land and others. All these data have been stored in one server called LRS Database Server which functions like a data warehouse for each land district in the country. However, the digital data security control that is being implemented for the system is not fully executed; as a result the volatile information is exposed to irresponsible people.

Literature Review

Information security, trust and culture the system security nowadays only focuses on the design of save and secure information system in operation. The complex information system security usually focuses something like the operating system, database, communication channels and user interface

secure. Sometimes many organizations do not aspect that information system security is very important in order to protect their privacy data. One of the major for organizational issues is to face the human factor in IT security because now day the system already become very vulnerable where employees, either deliberately or inadvertently, disclose such passwords to others, according to Jill (2003).

Work Area Controls

ICT archiving and particularly computer mediated communication mean that employees in the workplace can be monitored to unprecedented levels which show the web sites accessed, email traffic, email content or the use of video and audio facilities (Paul Jackson, Lisa Harris & Peter M. Eckersley,2003).

Desk policy implemented

The definition of a policy is "any course of action followed primarily because it is expedient or advantages in a material sense". When a company institutes a policy that promotes clean desks, overall it affects staff and employees across the board in a positive way.

Control A.7.3.1 of the standard requires the organization to implement a clear desk and clear screen policy to reduce the risk of unauthorized access to, or loss of, or damage to, information (Calder & Watkins, 2003). A clear desk policy is one of the easiest policies to adopt. It is important to ensure that appropriate facilities are available in the office in which computer media and paper can be stored and locked away, including in lockable pedestals, filing cabinets and cupboards.

Furthermore, according to Calder and Watkins (2003), personal computers, computer terminals and printers should be switch off when not in use and should be protected by locks, passwords and the like when they are not in use. Every personnel should be required to use a password for their personal computer or laptop which can prevent the data from being stolen.

Work practices controls are procedures for safe and proper work that are used to reduce the duration, frequency or intensity of exposure to hazard (Coombs, 2008). Notice there is some flexibility in the sample policy. When a policy is first adopted to encourage clean desks, it may be viewed as an extra burden in an already busy office, especially to those who work with layers of clutter and paper on their desk. The mindset of many of these individuals is that their messy desk doesn't affect anyone but them, but studies show that people with a messy desk waste 15 percent of their time looking for things (Sundblad, 2006).

Restricted access policy

Today there is no clear classification of modus operandi for illegal interference in computers, systems and networks functioning (Vehov, 1996). According to Golubev (2004), illegal interference in computers can be divided into 3 main groups:

The first group is ways of direct access to information. It covers damaging, deletion, deterioration, alteration, suppression or copying of computer data, and also serious hindering without right of computer, system or network functioning by inputting corresponding commands from the computer where information is stored. Direct access may be made by both persons working with data (related to this work), and persons intentionally penetrating in restricted areas or premises, where information is processed. It is necessary to note that today mentioned ways are the least spread in view of decentralization of information processing. In other words it is easier to intercept computer information during its transfer via telecommunication channels or computer networks, than in case of direct penetrating in premises. Now and then in order to seize information left by the user, offender looks around workplaces of programmers for drafts. On this purpose criminal may examine and/or restore erased software.

The second group includes ways of indirect (remote) access to information. Access without right to certain computer or information is made via computer networks from another computer, located at certain distance. Ways of indirect (remote) access are:

1. Connecting to telecommunication cables of authorized user (i.e. phone line) and obtaining access to his system.

2. Penetrating in other information systems by automated picking out of phone numbers of subscribers with further connection to their computers (picking out is carried out till the criminal receives the answer of the modem on the other side of phone line).

It is necessary to note that attempt of unauthorized access may be detected easily. That's why similar hack is carried out from several workplaces: at specified time several (more than 10) PCs perform attempt of unauthorized access. System security may prevent several "attacks" and others get desirable illegal access. One of the penetrated computers blocks network logging system that fixes all access attempts. In a result other penetrated computers may not be detected and allocated. Some of them start to hack certain sub network, other carry out fake operations in order to hinder functioning of the enterprise, institution, authority and cover up crime (Golubev & Urchenko, 1998).

3. Penetrating in computer network with help of passwords, pretending to be an authorized user. Using this method violators crack password on purpose to access other's computer. There is a number of specially developed software for these purposes. They may be purchased on the"shadow" computer market. Having got the right password (it takes less than 24 hours for choosing 8-digit password), illegal user obtains access to computer information and may use it whatever he likes: copy, delete, deteriorate, modify or suppress computer data, perform operations like wire transfers, forgery of payment orders, etc. as the authorized user.

The third group is made up by mixed methods that may be committed both by direct and indirect (remote) access. They are:

1. Secret insertions of commands in programs that allow performing new unplanned functions, making this program run able (program copies files, but simultaneously it deletes data on financial activity of enterprise);

2. Alteration of programs by way of secret placing of command sets that should snap into action under specified conditions in some time. E.g. as soon as the program illegally transfers money funds to so call false account, it will self-destruct and delete all the data on the committed operation.

3. Access to data bases and files of the authorized user through weak places in security systems. There arises an opportunity to read and examine information stored in the system, copy it, appeal for it in case of necessity. Thus one may appeal to data base of the competitor company and have an opportunity not only to analyze its financial state, but also obtain evident advantages in competition struggle;

4. Using bugs in programs and flaws. The program is "breaking" and malefactor inputs some amount of certain commands that help to perform new unplanned functions, making this program run able. Thus, one may transfer money to false accounts, obtain info on real estate, identities, etc.

Research Objective

The research objectives are as follows:

(i) to identify the information security control that being implemented in state and district.
(ii) to investigate the security awareness level of the personnel towards the information that being kept.
(iii) to analyze how far the security control being use and does it really help in protecting the information.

Methodology

This research strong emphasis is on descriptive research. The researcher conducted exploratory studies at the beginning of the research project to explore the topic being investigated. The specifics

of the problem and the variables involved were largely unclear at the beginning of the project. As Zikmund's (2002) observed, the project was started with a general statement that "there are information security controls in order to protect organization data." This opinion was formed upon the researcher's knowledge and practical experience working in the industry in this area.

This statement was further elaborated using the research methodology proposed by Booth, et al. (2003) to carry out the initial literature study and gather a better understanding of the dimensions of the problem. This exploratory study resulted in a set of approximately 40 questions seeking to answer the problems associated with the information security control focusing on LRS system.

The second phase consisted of the descriptive research, which was an extensive literature analysis seeking the answers to the approximately 40 problems identified during the exploratory research phase. This involved finding answers to very specific *who*, *what*, *when*, *where* and *how* questions. A framework of information security control was formed during this stage; variables were identified; and qualitative methods were defined. Below are the methods that being used for the research:

- Literature Review
- In-Depth Interviews
- Direct Observation
- Written Documents

Partial Framework

Findings

From the interviews and observations that had been conducted, the information security control that being implemented for LRS system at PTG and PTD was identified. There are a few issues that can be recognized as lack of information security controls towards the LRS system operation. The LRS operation include from customers' service counters to server room which store the LRS database server with valuable data about land in Selangor. The lack of information security controls can be recognized as a major inference towards the LRS database.

Work Area Controls

It was found that LRS system had implemented work area controls towards their operation floor.

Desk policy

It was found that LRS system activities involve counter transactions only. As a result, the management had found the importance to create a policy at the counter. The desk policy that being implemented at the counters was the counters desk must be clean and the stationary must be arranged accordingly. Besides, all the classified document should be place in the right location like a vault that being provided. It was called a clean desk policy. Based on the interviewed and observation, the counter personnel had followed the policy well. Both PTG and PTD site are following the desk policy and applied it accordingly. The implementation of desk policy had help out the PTG and PTD in protecting the important data stored in LRS database server by ensuring that all the classify document save in the vault.

Restricted access policy

Furthermore, it was found that there was a restricted access policy being applied to public people who needs to make a transaction using LRS system. The process just appear to be in front of the counter only, public people do not have a permission to go behind the counter. The execution of the policy is well implemented because the access door towards the LRS counter always close and there is a sign which showed only personnel can access the door. Both PTG and PTD site are following the restricted access policy and applied it accordingly. The implementation of restricted policy had ensured that the classified information could not be access by the public.

Workstation username and password policy

It was found that, in order to ensure only authorized personnel that can access the LRS system, the IT personnel had created username and password for each workstation that operate the LRS system whether in PTG or PTD. It will prevent the unauthorized user from accessing the system. There are a lot of departments in PTG and PTD which have many personnel work in the same roof. That is why the implementation of workstation username and password is very crucial not only to prevent access from public people but from their own staff also being prioritize. The implementation of username and password policy as one of the securities measured that had been taken in order to ensure the LRS data being protected.

Recommendation

Improvement Towards Physical Security

There is always solution to a problem. The problems of physical security at LRS server room in PTD and PTG. Based on an article written by Karen Duane Johnson (2008), she had included a comment by Christopher D. Marsden, chief technology officer and founder of Digitus Biometrics, as follows, “Biometric products assure categorically who that individual is as opposed to the use of cards, keys and key fobs. All we really knew before biometrics was that an item belonging to a certain person gained access to an area. In the next five to seven years biometrics will continue to be an ever important area of access control, as it is available now."

It is highly recommended that the server room which stores the LRS database server should be highly protected from being accessed by unauthorized user who might have hidden agenda. As an example, they can change the land owner’s name to someone else’s; they also can resize the land area and many other things that can be modified. The NRE Ministry should implement the finger print access towards all PTD and PTG server room in Malaysia. View Systems executive, Charlie Nelson states, "I think the benefits of this new application cannot be weighed. There are over 100,000 people on the most wanted list. I think this system provides a greater security measures because fingerprints don't lie." By using fingerprints system, only authorized personnel can gain access to the server room.

There were a few cases appear where the ownership and size of the land had been changed but it had been detected and a police report had been made according to Jabatan Penasihat Undang-Undang Negeri Perak. The data might be changed directly from the LRS server itself and it probably involves the insider. Besides the fingerprints system, the server room should be equipped with CCTV in order to monitor the personnel who have access to the server room. If some of the data had been changed suspiciously, we can look at the audit trail inside the LRS server and can make a match with the CCTV time frame if the personnel had made a modification towards the data.

Improving Security Policy Implementation

JKPTG had provided a security policy that must be followed by their IT officers. But some of them still do not realize how important for them to follow the security policy. As a solution to this problem, the management should give a talk about the security policy and describe how important for them to follow the policy. They also should be informed about the security breech that had happened before and the penalty waiting for them if they break the rules and the policy. It is difficult to make people follow the rules, but as an officer that who is responsible for the LRS database, they do not have any option except to follow the policy. Integrity should be observed at all time. That is why the

implementation of physical security will help a lot in securing the safety. For an example, even if an IT officer sticks the server password to the monitor, the password will be secured as long as the fingerprint system is working because unauthorized user could not have access to the room.

Solving the Backup Policy Implementation Problem

DGDLM had provided a backup policy for being followed by IT officer in district and state, but the same situation happens mirroring the password policy situation before. It is all about human awareness. Even though the management had provided training and had given them a direct order but the officers still could not adhere the policy. That is the nature of human being; everybody is prone to make mistakes. The information stored in LRS database can be classified as a very important data. From the statement above, the backup procedure is really important. Hence, the backup of the data should be done automatically by machine rather than relying on human being.

As a solution towards this matter, the implementation of data replication center should be the solution to the problem. Just look at the historic event that occurred in America before. The September 11th 2001 event had been recorded as one of the tragic catastrophe in this millennium. Thousands of people found dead. According to the statistic that being provided by Tom Templeton and Tom Lumley, there were 430 companies housed in WTC. Just imagine, can the organization survive after all their data had burned into ash? If the company had implemented data replication center in their organization, the company will survive for their organization data had been backed up.

Ministry of Natural Resources and Environment should realize how important the data or information that is stored in the LRS database, like the land number information, the size of the land, the owner of the land, type of land and others being stored in it. All the data is backed up by using a backup tape only. From my point of view, the important land information should have other alternative backup system and not only rely on the one way of backup system and also should not rely too much on human in order to make a backup towards the data.

The ministry should develop Data Replication Center which is able to store or backup all data from LRS database from each district and state. Just imagine, if one of the land district offices is involved in fire, all the server and backup tape will be destroyed. As well for sure the data is totally gone. How can the data be retrieved? It may take a few years to retrieve the data manually. A survey throughout the district needs to be conducted to identify every single land owner and record the necessary information. It is not only a crazy task to do but also a disaster to the ministry especially to the land district officer. According to Ahmad A. Abu-Musa (2004), he had conducted an empirical study on the Egyptian banking industry. He had found that backup copies should be placed in off-site storage and the sensitive data should be encrypted.

This is why Data Replication Center is necessary. It is almost a perfect solution for the disaster stated above. In Malaysia, all courts that have run e-SKHD (Revenue Collection and Deposit System) system have the database server and application server stored in each of their server room and once in two weeks the data in the database server will be copied to ABC Court Complex and then all the data from district and state including from ABC Court Complex are sent to Data Replication Center in Town XYZ. They use a dedicated line called PaduNet to transmit the data. This is the sample of what NRE Ministry should implement toward the district and state office including the headquarters in Putrajaya.

Data Replication Center (DRC) is a place to store the data or the place of mirroring data from original operation site. DRC is developed to secure the data in the operation site if disasters happen and the DRC will be located at a remote site. All the backup process procedure will be automated and will be controlled by replication server and the backup process will be executed according to the schedule and policy provided by the organization. Therefore, each state and district will have one replicate server to store data from LRS database and the data will then be transferred to storage warehouse located at the remote site. By implementing DRC in state and district, it will solve the data backup problem since all the backup procedure will be in automated mode.

Conclusion

There were a few weaknesses found at PTG and PTD regarding the information security control for LRS system. They can improve it by involving themselves with the current technology available in the market. In addition, the IT personnel should hire a consultant to give advice in order to improve the security control for LRS system. As stated in the findings, there had implemented the control policy but there was lack in the process of executing it. Some of the IT personnel are not aware about the important of securing the LRS data. As a result, they will not apply the policy in the daily task.

As for solution, the JKPTG should start educating their personnel in term of data security, the importance of the data and how to protect it from falling into irresponsible person. Besides, the values of integrity should be emphasized at all times. Furthermore, in developing new system in future, the front-end analysis and the design of the database should be prepared as perfectly as it can be in order to avoid data redundancy or data error and to ensure the integrity of the data.

Furthermore, by exposing or sending the IT personnel to seminar or IT workshop about security devices and control will enhance their knowledge and ideas. With the new information and knowledge, they can look after the loop hole at the LRS system and can make an improvement towards the information security control that had taken before.

Does Business Success Enhance With Firm's Age? Case of Croatian Food Manufacturing Industry

Maja Pervan, University of Split, Faculty of Economics, Split, Croatia, mpervan@efst.hr
Ivica Pervan, University of Split, Faculty of Economics, Split, Croatia, pervan@efst.hr
Marijana Ćurak, University of Split, Faculty of Economics, Split, Croatia, mcurak@efst.hr

Abstract

Although different aspects of firm's success have occupied researchers over the years, most researches that analysed this issue refer to the developed countries and, to a much lesser extent, to the developing countries, such as Croatia. However, in general there is a small number of researches examining the influence of firm's age on its success. In order to give contribution to this subject and enrich the understanding of firms' performance as firms get older, the authors conducted an analysis on a sample of 956 firms operating in the Croatian food manufacturing industry during the 2005-2014 period. The results of the dynamic panel analysis showed that firm performance deteriorates with age. As firms get older, benefits of their accumulated knowledge in all crucial aspects of the business (technology, supply channels, customers relations, human capital and financing costs) become overcome with their inertia, inflexibility and osseous by accumulated rules, routines and organizational structure. All control variables (size, liquidity, solvency, except gearing) proved to be statistically significant and in line with theoretical consideration.

Keywords: business success, firm's age, performance, food manufacturing industry, Croatia

1. Introduction

The question of whether larger (and/or older) firms are more profitable than their smaller counterparts have been in interest of numerous researchers for decades. Large amounts of theoretical as well as empirical research in different disciplines (economics, strategic management, finance) have been conducted in order to demystify this relationship. However, while some authors found a positive influence of firm size on its performance, the others found this relationship to be negative or non-existent. With regards to the firm age, the interest in this variable began to grow parallel with the studies that included firm age as an explanatory factor in investigations of determinants of firm performance i.e. business success. Although some theoretical explanations regarding the higher/lower level of profitability achieved by older firms are offered, due to the scarcity of empirical researches, no clear cut exist. One of the possible reasons for paucity of studies on this topic could be found in the absence of relevant data about the year of firm incorporation. Therefore, in order to exploit the benefits of Amadeus database and to give our contribution to the existing literature on this subject, in this research a role of firm age on business success is investigated on a panel of firms operating in the Croatian food manufacturing industry in the 2005-2014 period.

According to The Institute of Economics, food manufacturing industry has achieved the largest share in the gross domestic product and total employment, when compared to other manufacturing sectors in Croatia in 2014 (Ekonomski institut, 2015). More accurately, Croatian food industry has a long tradition and recognizable brands, and makes 28.2% of total production and 20% of total employment of manufacturing industry. The share of food industry in GDP in 2012 amounted to 3.2%. At the same time, the share of food production in GDP of the manufacturing industry accounted for 21.8%. Furthermore, the food industry in 2014 accounted for 8.8% of the total exports of manufacturing industry, and 7.7% in the total exports of the Republic of Croatia. When compared to the previous quarter, a production activity of this industry at EU-28 has increased by 0.43% in the last quarter of 2014 (Ekonomski institut, 2015). All these numbers clearly indicate the importance and significance as well as high potential that the Croatian food industry has, which as such should be recognized as strategic industrial sector of the Croatian economy.

The rest of the paper is organised as follows. An overview of the previous studies and their findings relating to the content being analysed is provided in section 2. Section 3 presents data, research

methodology and variable description, while section 4 gives insight into the sample description and econometric model including the empirical results. Section 5 presents concluding remarks.

2. Literature review

While some theoretical models considered the firm size as linearly related to firm age (Greiner, 1972), the others postulated specific predictions regarding the influence of firm age on its performance. Coad et al. (2013) summarized these predictions in three categories: selection effects, learning-by-doing effects, and inertia effects, depending on whether firm performance (expressed as a firm productivity) remains the same, increases or decreases over time. In empirical sense, firm age has been researched in different context. Starting with the influential work of Gibrat (1931) and finding that smaller, younger firms are more likely to grow faster than larger, older firms (in terms of the number of employees or amount of sales), a large number of researches have tried to explore the relationship between firm size and growth rate (see for example, Babirye et al., 2014; Bentzen et al., 2012; Palestrini, 2007; Evans,1987), as well as the relationship between firm age and growth rate (e.g. Barba Navaretti et al. 2014; Carr, 2010). While former relationships have usually turned out to be negative, no clear–cut has been made between firm age and survival (e.g. Bartelsman et al., 2005; Farinas and Moreno, 2000). Recently, some researchers were exploring a moderating effect of firm size or age on the relationship of analysed variables of interests like for example, relationship between institutional quality and export performance (LiPuma, 2013), relationship between organizational innovation, learning and performance (Hui et al., 2013) or relationship between R&D investment and firm performance (Fortune and Shelton, 2014), etc. Apart from the studies that were analysing a moderating effect of age in different industries/countries simultaneously, there were also studies that were concentrated on one specific industry (e.g. Ismail et al., 2014). A certain number of researchers have also examined differences in firm performance (profitability and/or productivity) at different stage of age.

Since the main focus of this research is oriented toward investigation of the nature of the relationship between firm age and its profitability, a brief presentation of recent empirical studies from this path of research follows. In order to observe whether older firms are more profitable because of their size or there is an age effect that can be revealed while controlling for firm size, Coad et al. (2013) explicitly included size and age variables in regression equation. With the application of different methodology (OLS, LAD, VAR) on the panel of Spanish manufacturing firms operating between 1998 and 2006, the authors found the evidence supporting both, improvements of firms with age (i.e. it was shown that the older firms were experiencing rising levels of profits, productivity, larger size, etc.) and deteriorations of firms performance with age (the results also revealed the lower profitability when others variables were controlled for; lower expected growth rates of profit, sales and productivity). On a sample of 1,020 Indian firms, Majumdar (1997) investigated whether the size and age of firms impacted firms' profitability and productivity. According to this author the age-performance relationship is environment-specific and dependent on a number of institutional factors, and hence cannot be analysed outside the institutional framework within which firms operate. The results of the conducted analysis showed that the older firms were more productive and less profitable, while the larger firms were more profitable and less productive. With the application of the maximum likelihood ordered logit estimates with robust standard errors, on a sample of 58,211 manufacturing and services firms observed over the period 2004-2012, Bruni et al. (2014) found a significantly negative sign of age variable on EBITDA to sales ratio.

Some researchers, in line with our study, focused their attention on only one particular industry. Bhayani's research covered the all listed cement firms operating in India during the period from 2001 to 2008 (Bhayani, 2010). With the utilization of the backward regression analysis, the results showed that the age of the firm (positive sign), together with some other internal and external variables (liquidity, operating profit ratio, interest rate and inflation rate), played a vital role in the determination of the firm profitability in Indian cement industry. Opposite to this study, on a sample of 57 business group companies of Indian nonmetallic mineral products industries, for the10-years period, Gaur (2011) examined the influence of different variables, among which the age variable as well, on operating profit and return on net worth, however, the age variable didn't prove to be statistically significant. Summarizing the results of the presented studies it becomes clear that the empirical researches regarding the relationship between the firm age and profitability remains

equivocal. Although a progress has been made in investigation of firm age on its performance, as noted by Coad et al. (2013), there are still many opportunities remaining for improving our understanding of how firm performance/behaviour changes as firms grow older.

3. Data, Research Methodology and Variables

The data for the research were collected from the AMADEUS database compiled by Bureau van Dijk. Since AMADEUS provides information at the 4-digit (NACE Rev. 2) level, the sample was created by including all firms recorded in any 4-digit NACE Rev. 2 food processing industry (categories between NACE-1011 and NACE-1099) for the period from 2005 to 2014. This industry was chosen due to its significant contribution to total manufacturing industry in terms of total production (28.2%), total employment (20%), and value of industrial production sold (17.6%), as well as due overall data availability.

AMADEUS has the advantage that it comprises firms of all possible size. This is an important issue since 95.3% of all firms operating in the EU food and drink industry are micro and small sized firms (FoodDrinkEurope, 2014). Therefore, unlike previous studies that were restricted to publicly quoted firms or that have used some minimum firm size criteria while constructing the research sample, the present study encompasses micro and small sized firms together with the medium-sized, large and very-large companies. Given that the total number of analysed firms was changing over the years (as a result of the entering of new firms in the market, mergers, acquisitions and liquidations), we were dealing with unbalanced panel (number of times-series observations was different across firms). After imposed restriction according to which only those companies that were active three consecutive years can constitute the sample, the total number of firms included in the analysis amounted to 956.

Descriptive statistics for all variables used in the analysis is shown in Table 1. The industry average is provided by mean along with the variables' minimum and maximum for period covered by analysis, while standard deviation indicates the interindustry variation of the variables value within the 2005-2014 period.

Table 1: Descriptive statistics

Variable	Obs	Mean	Std. Dev.	Min	Max
EBITDA Margin	5,928	8.862337	19.65476	-100	99.163
Age	8,565	13.10426	13.12341	1	123
Size	7,749	5.418349	2.40829	-5.94707	13.13784
Liquidity	7,598	1.821401	4.766754	0	96.375
Solvency	7,438	31.58373	34.19685	-99.513	100
Gearing	5,988	98.45579	166.3018	0	998.285

Source: Authors` calculations

Many of the economic relationships are dynamic in their nature and therefore, in order to evaluate the influence of firm age on its business success, we introduce a dynamic component into the model (1). Since lagged dependent variable also appears as an explanatory factor in the model, it correlates with the error term and strict exogeneity of the regressors no longer holds. Estimating model (1) via OLS would yields biased and inconsistent results. In order to overcome this problem and to obtain consistent estimator of δ, the authors used generalized methods of moments (GMM) panel estimator developed for dynamic panel models by Arellano and Bond (1991) and Arellano and Bover (1995). Discussion and various estimation methods for dynamic panel data are given by Baltagi (2005). Two-step estimator is employed on the following model:

$$\pi_{it} = \alpha + \delta\pi_{i,t-1} + \gamma Age_{it} + \sum_{c=1}^{C} \beta_c X_{it}^c + \varepsilon_{it} \qquad \varepsilon_{it} = \nu_i + u_{it} \qquad (1)$$

where π_{it} is the profitability of firm i at time t, with i=1, . . ., N, t=1, . .., T; α is a constant term, $\pi_{i,t-1}$ is the one-period lagged profitability, δ is the speed of adjustment to equilibrium, Age stands for firm

age, γ is the parameter of the variable of our interest - firm age, β_c is the vector of coefficients to be estimated, X_{it}^{c} is a set of the control variables, ε_{it} is the disturbance, with ν_i the unobserved firm-specific effect and u_{it} the idiosyncratic error.

All variables used in the analysis are chosen on the basis of relevant theory and empirical literature. The description of the chosen variables (i.e. EBITDA Margin, Age, Size, Liquidity, Solvency and Gearing) together with their expected influence on the firms' profitability is given in the following sections.

As a *dependent variable* (measure of profitability), we used *EBITDA Margin* which is calculated as a ratio of company's Earnings Before Interest, Taxes, Depreciation and Amortization, on one side, and its operating revenue, on the other side.

Age is used as a main *explanatory* variable in model (1). Since the focus of the present paper is put toward this variable, it is of interest to analyse and confront different theoretical aspects of the relationship between firm age and its performance. In theoretical discussion on age-performance relationship, the arguments can be found for both, positive and negative relationship. Argument for positive influence of age on performance lies in firm experience, since older firms can benefit from accumulated knowledge in all crucial aspects of the business (better technology, well-developed supply channels, well established customers relations, easier access to resources, better human capital and lower financing costs). As older firms have more experience, abilities and skills, and since they have enjoyed the benefits of learning, they consequently can enjoy superior performance. Although previously described arguments are quite convincing, so are those that stream to explain a negative influence of firm age on performance. As firms become older, they often try to codify decision making procedures, what makes them very bureaucratic, reduces organizational flexibility and ability for prompt changes. Rigid rules and procedures can be very large obstacle for organizational changes and innovation which are crucial in the modern globalized and very competitive business environment. Also, with the age firms might pursuit the strategy of "quiet life" and consequently avoiding risks (large R&D investments), large restructuring, conflicts with employees, etc. Avoidance of organizational changes and R&D investments in long term results in losing the competitive advantages and decreased performance. In line with this reasoning, a negative influence of this variable on profitability is anticipated. Age of the firm is expressed by the number of years that firm operates in the market.

Control variables. In order to control for different firms' characteristics, a set of control variables is introduced in the analysis. Each of the control variables captures specific aspect of firms' activity. Thus for example, *Size* variable had task to control for firm size, since size of a firm can serve as a source of economies and diseconomies of scale (Besanko and Braeutigam, 2011), therefore both, positive or negative sign of this variable may appear. *Liquidity* represents firm's ability to settle short-term liabilities resulting mainly from operating costs. Current liquidity is often calculated as ratio of current assets and current liabilities. Firm should maintain required level of current assets in order to cover current liabilities and according to theoretical consideration the optimal ratio of this variable should equal 2. Alternative measure of liquidity, the quick liquidity (Current Assets-Stocks/Current Liabilities), which is used in this research, should be at least 1. Liquidity below ideal values indicates that firm is not liquid and consequently cannot settle its current liabilities. Illiquidity is often consequence of poor operations and can be related with lower firm performance. On the other hand if firm overinvests current assets it can also negatively affect business success due to higher financing costs in overinvested current assets. Having in mind previously described characteristics of liquidity, this variable can have both, positive or negative influence on firm performance. *Solvency* describes firm's financial health and capacity to repay long-term liabilities. In line with theoretical aspects, shareholders' funds should cover at least 50% of total assets. If shareholders' funds fall significantly below 50%, firms' risk of default/bankruptcy rises, what is often reflected in higher financing costs and lower performance. Therefore, it is to expect that the higher solvency should result in higher performance, i.e. a positive sign of solvency variable is to be anticipated. Finally, the *Gearing ratio* measures the structure of financing sources, i.e. ratio of long term borrowings and shareholders' funds. Firm growth often requires financing by long term debt which increases gearing and firm risk. Namely, highly leveraged firms are perceived as more risky since in period of economic downturn firm must repay its debts regardless of negative trends in sales and cash flows.

Without long term debt firms could not achieve required level of investments and therefore certain level of gearing is necessary. Therefore, financial managers in firms should achieve optimal level of gearing, while having in mind that too high level of gearing might significantly increase insolvency/bankruptcy risk and financing costs. On the basis of previous discussion we expect that gearing negatively affects firm performance.

Summary of the variables and corresponding measurements is presented in Table 2.

Table 2: Measurement of Variables

Variables	Measurements
Dependent	
EBITDA Margin	(Earnings Before Interest, Taxes, Depreciation and Amortization) / Operating revenue
Independent	
Age	Number of years that firm operates in the market
Size	Logarithm of total assets
Liquidity	(Current assets - Stocks) / Current liabilities
Solvency	(Shareholders funds / Total assets) * 100
Gearing	((Non current liabilities + Loans) / Shareholders funds) * 100

4. Results and discussion

Pairwise correlation matrix is shown in Table 3, while Table 4 presents the results of the dynamic panel analysis estimated using two-step General Method of Moments (GMM) as proposed by Arellano-Bond. Most of the correlation coefficients demonstrate weak correlation between variables. The highest value of the coefficient is obtained between Solvency and Gearing variable and amounts to -0.5087, which is still far below the acceptable level and possibility that problem of multicollinearity occurs.

Table 3: Pairwise correlation

Variable	EBITDA Margin	Age	Size	Liquidity	Solvency	Gearing
EBITDA Margin	1					
Age	0.0244	1				
Size	0.0898	0.4813	1			
Liquidity	0.1496	0.0228	-0.0388	1		
Solvency	0.2305	0.2108	0.1144	0.3469	1	
Gearing	0.0143	-0.0507	0.1523	-0.1281	-0.5087	1

Source: Authors` calculations

For consistent estimation, GMM estimator requires that the error is serially uncorrelated. First-order and second-order serial correlation in the first-differenced residuals is tested using m_1 and m_2 Arellano and Bond test statistics. The GMM system estimator is consistent if there is no second-order serial correlation in residuals (m_2 statistic). This means that the presence of a first-order autocorrelation in the differenced residuals does not imply that the estimates are inconsistent (Anderson and Hsiao, 1981). Another important test in dynamic panel analysis is Sargan test. This test checks for overall validity of instruments. If a null hypothesis is accepted, meaning that overidentifying restrictions (all chosen instruments) are valid, the dynamic panel model is adequately specified.

Table 4: Parameter estimates of dynamic panel model

Variables	EBITDA Margin	
	Coef.	**P>|z|**
EBITDA Margin$_{(t-1)}$	0.35018	0.000
Age	-1.25855	0.000
Size	6.80065	0.000
Liquidity	-0.41186	0.017
Solvency	0.19775	0.000
Gearing	-0.0021	0.398
Cons	-22.6728	0.001
No. of observations	3,157	
Sargan test (p-value)	0.5641	
Arellano -Bond *(m_1)*(p-value)	0.0000	
Arellano -Bond *(m_2)* (p-value)	0.4149	

Source: Authors` calculations

With regard to the statistical tests, empirical results obtained for the model (1) show no presence of second-order autocorrelation. Likewise, Sargan test shows no evidence of over-identifying restrictions. This suggests that the dynamic panel model is adequately specified. Furthermore, table 4 reveals that lagged profitability variable (EBITDA Margin$_{t-1}$) has statistically significant influence on current firms' profitability which confirms the dynamic character of the model specification. Regarding the main variable of our interest (Age), it can be perceived that, after controlling for other influences, firm age has statistically significant negative influence of firm's performance. This finding indicates that for the firms operating in Croatian food manufacturing industry, one can expect deterioration of firm performance as time goes by. This finding is opposite to that of Bhayani (2010), but in line with those of Majumdar (1997), Coad et al. (2013) and Bruni et al. (2014), and can be interpreted in a way that due to bureaucratic ossification older firms become inert, without required flexibility to adapt to new business circumstances and therefore they are likely to be outperformed by younger, more flexible firms.

It should be noted that selected control variables (except *Gearing*) have statistically significant influence on firm performance i.e. business success. The sign of the coefficients of all control variables are in line with our expectations. More precisely, positive sign of *Size* variable indicates that firms may exploit economies of scale and scope, and therefore benefit as becoming larger. Also, firms with higher *Solvency* perform better, pointing that they are perceived less risky and therefore can operate with lower financing costs. The results also indicate that firms with lower *Liquidity* achieve better performance, i.e. strategy of minimizing working capital can increase the firm performance. Finally, although the negative sign of the coefficient of *Gearing* variable indicates that increased leverage reduces performance, this variable is not statistically significant. In general, apart from the fact that the coefficient signs of the explanatory variables are in line with the expectations, they are also comparable with findings from previous studies (Pervan, 2013; Vijayakumar, 2011; Obert and Fatoki, 2010; Feeny et al. 2005).

5. Conclusion

The aim of this research was to determine the extent and nature of the relationships (if any) between firm age and business success. The analysis is conducted on firms operating in Croatian food processing industry for the period from 2005 to 2014. The total number of firms included in the analysis amounted to 956. Given that the total number of analysed firms was changing over the years (as a result of entering of new firms, the mergers, acquisitions and liquidations), an unbalanced panel is formed. Food processing industry was chosen due to its significant contribution to total manufacturing industry in terms of total production (28.2%), total employment (20%), and value of industrial production sold (17,6%) as well as due overall data availability.

The results of the conducted dynamic panel analysis reveal that age of firms plays important explanatory factor in determination of business success. Precisely, on a sample of Croatian food processing industry, firm age turns out to be statistically significant with negative coefficient sign, thus suggesting deterioration of firm performance with age. As firms grow older, they become very bureaucratic, with reduced organizational flexibility and ability for prompt changes. Also, firms might pursuit the strategy of "quiet life" and consequently avoid risks, large restructuring, conflicts with employees, etc. As regards the control variables that have task to capture different firms' characteristics, the results of the conducted analysis indicate a positive and significant influence of firm size and solvency on business success, as well as significant and negative influence of liquidity. Gearing variable didn't prove to be statistically significant.

Overall, the present study enriches our understanding of firm age and performance in Croatian food manufacturing industry and highlights the importance that some other variables, aside from age, may have on business success. From a manager policy perspective, the obtained results provide guidelines in formulation of adequate business strategies and points to factors that managers must take into account in order to achieve better firm performance. Further researches may be oriented toward investigation of presence/existence of non-linear age-performance relationship, with its application on a broader research sample together with the inclusion of additional explanatory/control variables.

Abstract

This article present the results of the research conducted in the direction of the role of innovation in the current economic globalization. In today's highly dynamic and competitive business environment, firms are exposed to strict challenges with meeting the ever-increasing market and customer needs and expectations. In order to ensure the competiveness and success of the organization managers need to accept innovation as a key element for the organization. The aim of this paper is to highlight the importance of innovation in today's economy. The importance and the need for innovation result from its contribution to enhancing the productivity, competitiveness, economic performance and social objectives. Few managers have a wider vision which includes innovation, allowing a better performance of the activities. Companies need radical changes not only for products or services, but also for their business strategies. Unfortunately there is still no common understanding (and correct) of the term innovation among managers. Furthermore, not all managers are aware of the need for innovation. Under these conditions, increasing the adaptive processes of firms (through innovation) to meet the needs and performance requirements is difficult to accomplish in the absence of a systematic framework. We have analyzed the concept of innovation and its evolution in the scientific literature over time, its importance for EU member states and in the end of the paper we have identify some new research direction regarding innovation.

Keywords: innovation, innovation process, importance of innovation, economic globalization.

Introduction

Innovation is now a very used term in the business environment, but is not a new concept, it exist since the early twentieth century, when Austrian scientist J. Schumpeter analyzed innovation from economical point of view. He defined innovation as all changes in order to implement and use the new types of products, means of production and transport, markets and forms of organization of production. In his researches Schumpeter indicate innovation as the main source of profit for an organization. He said that, in essence, profit is the result of developing new combinations and without development there is not profit and vice versa, without profit there is no development, as in Purcarea (2011).

Even if in essence innovation seems to be a simple concept, the variety of studies regarding innovation since 1934, have proven the complexity of innovation, thus the literature offer a variety of definitions for innovation, each researcher trying to capture better and more accurate the process of innovation. In this research we consider innovation defined, according to the OECD (2005) - Organization for Economic Co-operation and Development - as the implementation of a new or significantly improved product (good or service), or process, a new marketing method, or a new organizational method in business practices, workplace organization or external relations.

In the current era, characterized by economic globalization - which requires trade liberalization and lowering costs in communications - the developed countries must compete with countries that have a

workforce poorly paid, although well-educated – innovation have an important place. And if we add also the progress of science and technology we can observe that innovative organizations benefit more from opportunities and competitive advantages.

The innovation process is one of the most important factors behind the growth and prosperity of the global economy today but this is poorly understood. Over the last century, industry leaders have learned to master the production process to such an extent that today it is not a significant competitive advantage. The new challenge is to master the process of innovation – capitalizing change, creating new competitive advantages by offering better products by using better processes, providing better service or offering entirely new solutions.

2. Evolution of Innovation Importance in Scientific Literature

In the current context, characterized by economic globalization, innovation is one of the most important tools for organizations all over the world. This importance is felled also in the academic and research environment, this can be highlighted by the number of articles published in the scientific literature in the last years. In this sense we performed a search in the most important scientific database in the world, ISI Web of Knowledge, by the word "innovation".

The results of the search indicate a number of over 340 000 articles that have the word innovation in their topics. For a better understanding of the interest for innovation in the scientific area we grouped the article by years of publishing illustrated in figure 1.

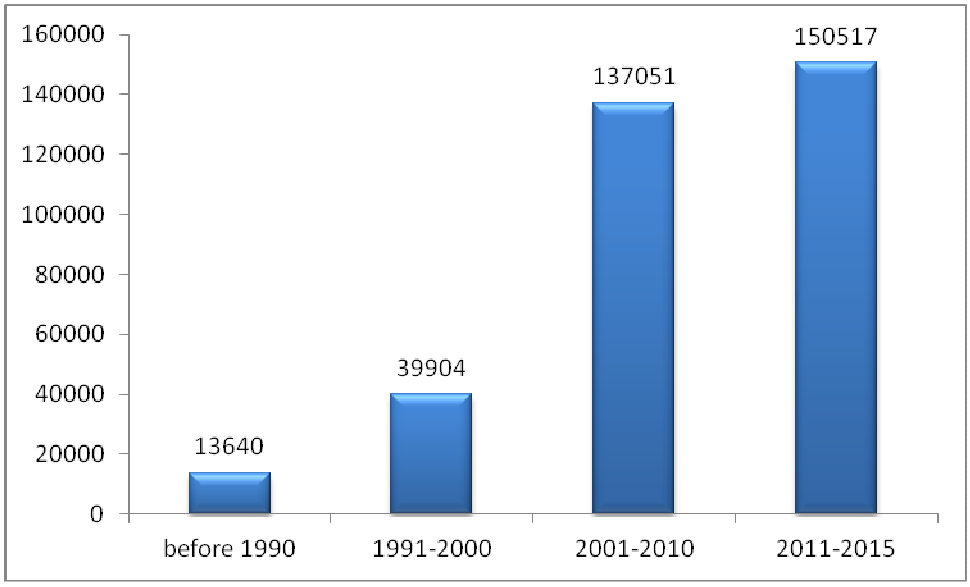

Fig 1. Evolution of published articles regarding innovation in ISI Web of Knowledge database (processing of the authors)

As it can be seen in figure 1, the numbers of article where innovation is mentioned has increased very much in the last years. Before 1990, in the ISI Web of Knowledge database, were mentioned 13 640 articles, in the following 10 years between 1991 and 2000 the number of articles has increased to almost 40 000 articles. In the next period of ten years, between 2001 and 2010, we can observe a huge increase of articles dealing with innovation, form almost 40000 articles to over 137 000 articles. The interest for innovation is increasing, thus in the last five years, from 2011 to 2015 over 150 000

articles have been published, more than the number of articles published in a period of 10 years previous to 2011.

More than that we can compare the total number of 167 888 articles published before 2010 (without articles published in 2010) with the number of articles published after 2010 (including articles published in 2010) which is 169 195 articles. We can observe that in the last five years the articles involving innovation have already surpassed the total amount of articles published before 2010.

This high interest for innovation in the last years can be explained by the current specific features of the business environment. These features tend to be more pronounced with the intensifying global competition and the tendency of customization of client requirements, thus leading to compressing the time period between consumer perception of certain needs and the launch a new product to satisfy these needs. Thus the one of the important characteristic for the competitiveness of an organization is the ability to react quickly to changes in the business environment, especially in areas where the rate of technological change is high and production cycles are short.

Even if in the current economic context, innovation is one of the most used terms, our past studies (Maier, 2013; Maier, 2014; Maier, 2015) reveal that it is still not well understood especially due to its complexity and the multitude of specific characteristics of each activity sector. Most of the managers expect for a universal tool, technique or even a spell that once is applied it transform a noninnovative organization in an innovative one. But such a tool does not exist, not because nobody thought about it or nobody tried to developed one, but in our opinion because with the current knowledge it is not possible to have one. There are multiple attempts to develop several frameworks for managing innovation, including our studies in Maier (2014; 2015), but in most cases the final results is a general innovation identifier that can offer the manager a sense of the state of innovation in his organization and some direction to follow in order to become a innovator.

This unpredictable character of innovation led to a wealth of failed innovation projects over time. However the lack of innovative projects is not a solution, this was felled even by large companies that were once precursors and creators of all markets, but they have failed to remain competitive when major changes occurred, particularly the technological changes. Organizations tend to developed themselves and to get used with what they do (basic skills) suck that they get stuck there, and when the environment changes (ex. Changing customer requirements, changing regulations) they are unable to adapt quickly and easily (Vlachaki, 2010).

3. Importance of Innovation for the EU Member States.

Innovation in today economic context is important not only for companies but also for the prosperity of the countries. To highlight the importance of innovation in a globalized economy and its connection to the prosperity of the countries we have analyzed the study performed by European Commission regarding the innovation performance of each member state of European Union. The results of the study were published in 2015, and according to the overall innovation performance each member state can be classified in four categories: Innovation leaders; Innovation flowers; Moderate innovators and Modest innovators.

The average annual growth of innovation performance in the EU was 1.6% in 2008-2012, many countries improving their innovation system in this period. In figure 2 we can observe the innovation performance for every state of the European Union.

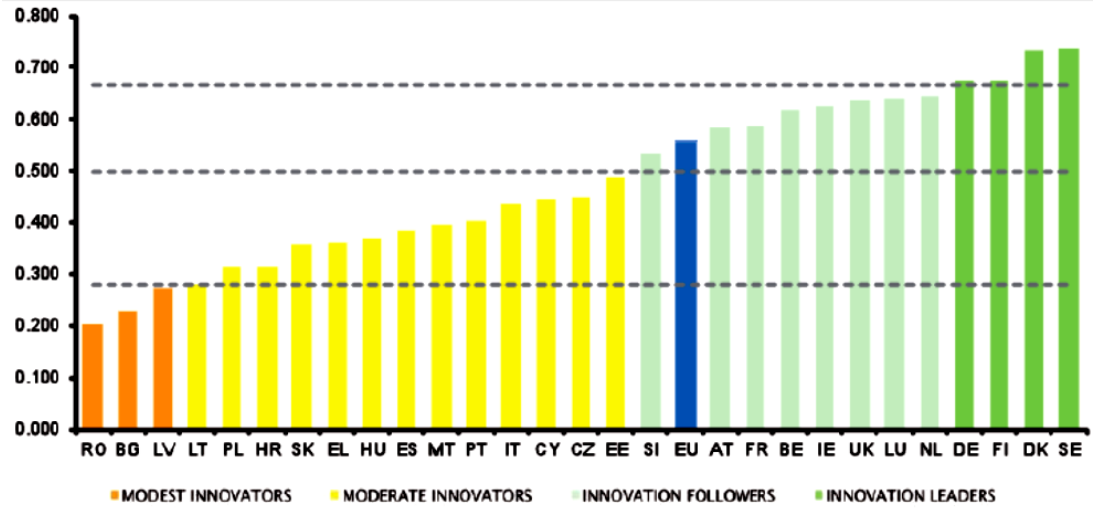

Figure 2. EU Member State's innovation performance (*, 2015)**

As it is shown in figure 2, Sweden ranks first from EU members regarding innovation performance. The other states that are grouped in "Innovation leaders" category are Germany, Finland and Denmark; these countries have innovation performances well above the EU average. The second category "Innovation followers", are countries with innovation performances above or close to that of the EU average. In this category are included: Austria, Belgium, France, Ireland, Luxembourg, Netherlands, Slovenia and the UK.

Another group of countries have the innovation performances below that of the EU average, this group are "Moderate innovators" and are formed by Croatia, Cyprus, Czech Republic, Estonia, Greece, Hungary, Italy, Lithuania, Malta, Poland, Portugal, Slovakia and Spain. The last category is formed by Bulgaria, Latvia and Romania, with innovative performance well below that of the EU average and they are "Modest innovators".

This classification of EU member states, from innovation performance point of view somewhat respect the economic power of the countries. It can be observe that well developed countries have a high innovation performance than the less developed one. The aim of this article is not to present the factors that led to a greater innovation performance, or to identify the causes why developed countries have better innovation systems. By using this classification we want just to highlight the connection between innovation performance and the degree of development of a country. In the same manner if we narrow down to the organizational level we can consider that for a company to be more competitive, more profitable and to have the power to develop, innovation is a characteristic that must be nurture.

4. New Direction Regarding Innovation

If until three decades ago, almost every objective of an organization where approach from the economic efficiency point of view, nowadays the intense development of the human activities oblige companies to take into consideration other aspects related to their activity. There is a great interest for innovation both in the academic area and among practitioners. This interest is more pronounced in today's globalized economy and in this case new solution for a better understanding of innovation or for obtaining better results from innovation is needed. For an organization which has difficulties to survive or for every organization the adoption of an innovative culture is not an easy process, thus a new approach related to the innovation tend to develop. In 2003 Henry W. Chesbrough introduced the term of open innovation. He observes that many of the organization started to rethink the way they manage innovation. Until then the predominant idea was that every organization should manage

and control the innovation process from the first step to the last one and that in order to be successful every organization must control and work alone for innovative projects, mentioned in Olaru (2015).

The new approach proposed by Chesbrough describe a process in which the company wants to acquire external collaborations ideas or new technologies to exploit their assets and establish alternate routes to market during the innovation cycle. Therefore, the boundaries between enterprise and the environment become less restrictive and allow two-way interactions, inwardly and outward.

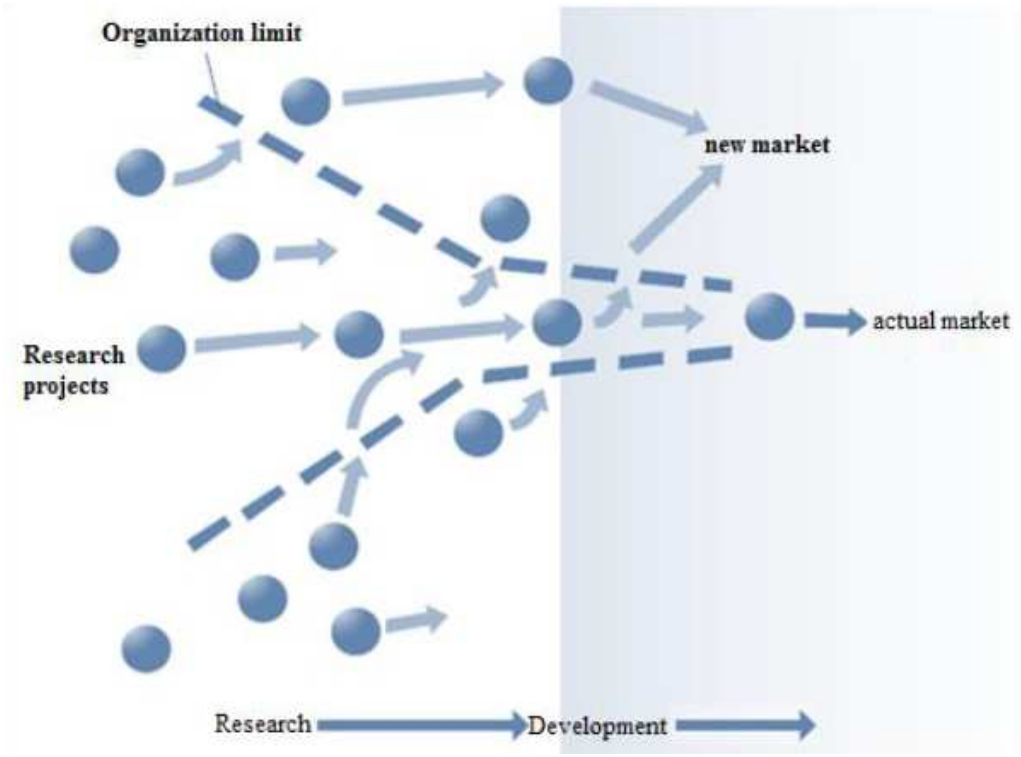

Fig 3. Characteristics of open innovation (processed by the author after Chesbrough, 2003)

The main principles of open innovation can be resumed to:

- Not all intelligent people work within the organization. However, the company should try to find them and work with them inside or outside its border.
- A better business model is preferable to the detriment of the primacy of the market.
- Internal innovation efforts are needed to harness external innovation efforts.
- The key to success is not generating as many ideas as possible, but efficient use of internal and external ideas;
- An undertaking should not block its intellectual properties. Instead, it should consider selling or buying intellectual assets whenever it is beneficial to his model

By applying the above principles some advantages can be obtained, such as:

- Finding new and innovative ideas;
- Development of new and innovative products and services;
- Risk-sharing and cost reduction and R & D;
- New markets;
- Increasing reputation;
- Shortening the time to enter the market.

Open innovation is now one of the most debated topics in management literature. However, there are still many unanswered questions in innovation. In particular, two issues need further investigation, namely, understanding the relevance of open innovation and how companies implement open innovation in practice.

Open innovation paradigm is implemented over a process that is conducted in three phases comprising the steps: unfreezing, movement and institutionalization. In some research study as Chiaroni (2011) and Huizingh (2011) is mentioned that moreover, it turns out that the changes that open innovation has been implemented involving four large, ie networks, organizational structures, processes evaluation and knowledge management systems. It should, therefore, managerial and organizational levers designed as an innovative organizations.

5. Conclusions

The current economic environment, strongly hit by the economic crisis, obliges organizations to face increasingly heavier conditions. A fierce competition, brief market niches, and frequent changes in product demand characterize the new economic environment, a globalized one. The organizations will have to face more and more frequently and unpredictable changes on the globalized market. In order to be competitive and to be able to capitalize any opportunity, the organizations will have to develop new ways of management, which has to adapt and to be able to predict, as quickly as possible, the apparition of various changes. . A key consideration for companies is their ability to adapt and innovate. The purpose of innovation is mostly to survive, to grow, to make a profit, but what matters for innovation is how it affects the chances of survival, profit and growth opportunities.

Email: ahed.abugabah@zu.ac.ae

Abstract

Organizations depend heavily on information systems and their outputs to achieve organizational goals and facilitate main business processes. Quality of system's outputs "information quality" is considered an important ingredient of information system's outputs as it determines the degree to which information is used in organizations. Quality of the system itself is also a critical factor that determines the level of information quality and system features that consequently affect the system utilization and benefits gained by the system users. This study focuses on user perspectives and how users perceive the characteristics of information quality. The study aims at providing a more incorporative framework and measurements to information quality of information systems. It also aims at measuring the perceived impact of information quality on user evaluation and performance. Consisting with previous studies, the study provides some useful conclusions that can be used by managers to structure their information system strategies to best benefit their organizations. The study gained evidence supporting strong relationships between information quality and user evaluation of the information systems. The results indicated that information quality and systems quality are significant determinants of utilization and usefulness, obtained when using information systems.

Keywords: Information Systems, System Quality, User Evaluation, Information Quality

1. Introduction

Increased organizational dependence on information systems and their outputs drive management attention towards improving information systems' quality and output quality of the systems. Recent studies have showed that improved information systems quality is a serious concern facing both business managers and information technology professionals. Quality in information systems field is a multidimensional measure, it is important to determine what aspects of information systems are critical to both organizations and individual and how individuals perceive better benefits when using information systems (Gorla, Somers& Wong, 2010).

Information quality depends on user perceptions of the value of the IS output. Thus, most of its measures are perceptual, including accuracy, precision, currency, output timeliness, reliability, completeness, conciseness, format, relevance, understandability, report usefulness, etc. DeLone, & McLean, (2003) characterized system quality, as the degree to which a system possesses desired characteristics, and measured it using four factors: convenience of information, system flexibility, system integration, and response time. Since system quality measures the information processing system itself, the background characteristics of the system under study need to be outlined before developing any measurements.

The quality of information, provided by an information system, is a very important factor in leading people to believe in the usefulness of that information system. When people feel that an information system is useful to them, the chances that they will utilize that system will be higher. If the information provided an information system is vague, erroneous, or incomplete, it will arouse doubts in the user's mind about the reliability of that particular information system and possible harmful opportunistic behaviours and thus, reducing intention to use. On the contrary, an information system that provides high content quality will increase intention of users to engage in the services provided. This study is a part of a large project focuses on user evaluation of hospital information systems and how users perceive the characteristics of information quality of these systems. The study aims at

providing a more incorporative framework and measurements to information quality. It also aims at measuring the perceived impact of information quality on user evaluation in healthcare organizations.

2. Literature review

2.1. Information Quality

Information Quality (IQ) is considered an important ingredient of IS outputs as it determines the degree to which information is used in organizations (Pitt & Kavan, 1999). As a result, IQ research activities have increased significantly to meet the needs of organizations attempting either to measure or provide a rigorous framework for IQ (DeLone, & McLean, 2003). In view of that, there have been many different frameworks of IQ. However, even though these classifications differ in detail and in the names of the IQ measures, there are substantial overlaps among them. Furthermore, despite a decade of active research and practice, the field lacks comprehensive methodologies for its assessment and improvement.

Typically, the IQ assessment framework means classifying the IQ factors so that they are testable and provides an extensive template for applications in a specific domain. In this sense, an IQ model assessment means a multidimensional structure consisting of theoretical concepts, terms and relations that identify the main characteristics of information (Slone, 2006; Besik, 2006). Information characteristics have been viewed as important determinants of IQ, which include accuracy, precision, currency, output timeliness, completeness, format, and relevance. Others, however, have highlighted the domain and purpose of the interest to the information users as main characteristics of IQ or the degree to which information satisfies user requirements or is suitable for a specific process. Therefore, IQ in total refers to its user's requirements (Wang & Strong, 1996).

2.2. Measures of information quality

The IQ literature reflects the existence of a number of views on what constitutes the attributes of information. A significant number of empirical studies have been conducted to develop a framework to measure IQ. Starting from the many characteristics identified by (Bailey & Pearson, 1983) such as accuracy, precision, currency, timeliness, completeness, conciseness, format and relevance. Najjar (2002) later identified five IQ characteristics of accuracy, timeliness, conciseness, convenience and relevance. Sometimes, measures of IQ focus on the output produced by a system and/or the value, usefulness or relative importance attributed to it by the user. In this sense, Huang, Lee, & Wang (1999) conducted a series of studies on IQ and used accuracy, relevancy and accessibility to measure IQ.

Among several studies, researchers sometimes mixed these IQ measures based on the purpose or scope of the study. Miller, (2007) used terms of usefulness, accuracy, timeliness and relevancy to measure IQ, while Alka, (2001) used clarity, relevancy, accuracy and timeliness in her research. In a similar vein, Bovee (2004) used relevancy, accessibility, accuracy and interpretability. Eventually, from the user perspective, a framework was developed to capture the underlying IQ in four grouped classifications

- Intrinsic, consisting of believability, accuracy and objectivity.
- Contextual, consisting of relevancy, timeliness and completeness.
- Representational consisting of interpretability and ease of understanding.
- Accessible, consisting of accessibility and access security.

The above framework was repeatedly used in a substantial amount of prior research and was based on several studies that aimed to identify the most relevant characterises of measuring IQ. To conclude, prior research provided a thorough classification of IQ measures, notwithstanding discrepancies in the definitions of most measures due to the contextual nature of both quality and IQ. However, the literature lacks a comprehensive framework that researchers and organizations can apply. Thus, by analysing these classifications, it seems possible to formulate a basic model for this study. The most commonly and widely accepted identified IQ characteristics are presented in (Wu & Wang, 2006). This study therefore consolidates these commonly used characteristics to build an IQ framework that

includes relevancy, accuracy, timeliness (currency), appropriate amount (completeness) and accessibility, as discussed below:

2.2.1. Relevancy

A key component of IQ is whether or not the information addresses the user's needs. If not, a user will find the information inadequate. Thus, relevancy refers to the degree to which the information is appropriate for the users' tasks (Solomon, Terry, & Magid, 2003). Relevancy refers to the extent to which information is applicable and helpful in performing the task at hand. Relevancy therefore links the information to the users' needs besides task requirements. Solomon, Terry, & Magid, (2003) stated that with access to information, which can be interpreted, one needs to know if it is relevant to the domain and purpose of interest to the user. Therefore, relevancy is a critical element for IQ, making information understandable and interpretable to users and helping them use all the information that is essential to their task and to avoid any irrelevant information.

2.2.2. Accuracy

Accuracy is defined as the correctness of the output information provided by a system. Researchers have discussed this concept as the main part of IQ. For example, they proposed that accuracy is the extent to which information is correct and reliable, which others call "free of error" (Alloway, 2007). Generally, it is believed that accuracy of information is a critical issue for users as they utilize information for various purposes. Therefore, if the information is accurate, performance will be more efficient with fewer mistakes, meaning that accuracy affects work outcomes by reducing the errors caused by inaccurate information and leading to higher quality performance.

2.2.3. Timeliness (currency)

Timeliness pertains to the degree to which information is perceived to be current Bovee, 2004). Therefore, timeliness is an important component of IQ, because it gives the information currency increasing information value for users and reflecting the age of the information. Timeliness refers to currency and validity. Currency refers to the age of the recorded value, while validity refers to the length of time the value remained valid. Therefore, information must be updated continuously to fit the users' needs. However, others contended that information does not wear out. Nevertheless, as it ages, it bears less and less correspondence to the real or conceptual thing(s) it is associated with. Thus, the time from the collection of a value to its recording and the speed with which the source of the value changes over time are critical considerations for IQ Solomon, Terry, & Magid, 2003; Alloway, 2007; Floropoulos, Spathis, Halvatzis, & Tsipouridou, 2010).

Generally, timeliness is always related to updating aspects and it captures how often data changes or how often new data is created in the system (Calisir & Calisir, 2004). The updating process can increase the importance and value of information and make the information appropriate for user needs and tasks.

2.2.4. Appropriate amount (completeness)

Completeness refers to the comprehensiveness of the output information provided by a system. Information must be provided in an appropriate amount; too large volumes of information may make it difficult for users to access. In this regard, information needs to be sufficiently complete according to the users' domain, purposes and interests. This would help users complete their tasks on time and avoid any delay in delivering the outcomes, leading to more improved performance (Floropoulos et al, 2010).

2.2.5. Accessibility

Accessible information can be obtained when needed. Accessibility depends on the user and even the specific circumstances of that user. Basically, accessibility emphasizes that information must be accessible, but secure for all users. If the information is accessible to users and convenient when needed, users will be able to accomplish their tasks with a high degree of satisfaction achieving maximum potential usage of a system, leading consequently to more system impact on performance (Miller, 2007).

3. Research Methods

This study focuses on IQ and SQ measures and their perceived impacts on user evaluation and performance. The study was conducted in enterprises utilizing Enterprise Resource Planning Systems (ERP) with the aim of testing the impacts played by above mentioned factors and subsequent measures on user evaluation of the systems utilized. The study factors and their proposed relationships are illustrated in figure 1.

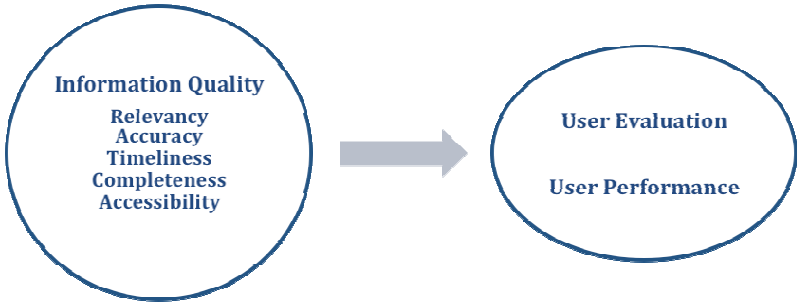

Figure 1. The Study Model

3.1. Hypotheses

In light of the above discussion and the review of the literature regarding both SQ and IQ, the current study tests a set of hypotheses as follows

Information quality will be positively related to user evaluation of information systems.

Information quality will be positively related to perceived user performance.

3.2. Sample, Procedure and Instruments

The population of this study was enterprise systems users in two hospitals. The inclusion criterion of sample selection is users who had experience using the hospital information systems in their work. A total of 203 users from deferent departments were surveyed. The method used to gather information in this research was through questionnaires composed of measures. The questionnaires were gleaned and compiled from previous validated instruments. However, some modifications were made to wording to suit the context of the health enterprise systems. Items were adapted from previous literature of system quality and information quality (DeLone & McLean, 2003). Most items were rated on a Likert-7 point scale of 1-7 (1 = strongly disagree, 4 = neutral and 7 = strongly agree). The data gathered questionnaires were checked to ensure their suitability and completeness. 6 questionnaires were excluded from further analysis due to incompleteness. A total number of 197 questioners were analyzed using SPSS software. Factors analysis and regression analysis were used to test the study model and examine the relationship between the study factors as explained in the nest section.

4. Discussion and Findings

4.1. The impact of information quality on user evaluation

The impact of IQ on user evaluation of the system impacts was measured by accuracy, relevancy, timeliness, completeness and accessibility. The results of the analysis indicate that IQ affects user evaluation positively; the whole model was significant and positive ($F = 227$, $df = 2, 384$, $R = .609$, $P < .01$), reflecting strongly significant and positive impacts of the IQ on perceived user performance and evaluation of the system, explaining 37.1% of the variance in user performance ($R^2 = .371$, $\beta = .606$).

Table 1. Regression analysis for IQ and user evaluation

Factor	*B*	*S.E*	*β*	R	R^2	*F*	*t*	*Sig*
Constant	.364	.278					1.312	.190
IQ	1.147	.076	.609	.609	.371	227	15.061	.001
The results of stepwise regression								
Factor	R	R^2	Adjusted R^2	*β*			S.E	Sig
Completeness	.557	.310	.308	.341			.949	.001
Accuracy	.597	.356	.353	.213			.918	.002
Timeliness	.618	.383	.378	.197			.900	.001

The result was further explored using stepwise regression to identify the most important factors of IQ that affect user evaluation from the user's perspective. As shown in the Table 2, based on the β value (β = .341), completeness or the volume of the information was the most important measure of IQ that contributes significantly to user performance. Therefore, users pay high attention to the quantity of the information or the degree of completeness of the information. Similarly, accuracy was found to be an effective factor that affects user evaluation of the systems. The last factor in the model was timeliness, or getting the information in a timely manner. This factor also contributes significantly to user evaluation and perceived performance and adds a unique value to the whole model, (β = .197). Getting updated information from the systems on time helps users improve their performance. It also helps improve performance efficiency and effectiveness, because it saves the user's time. In respect to the other factors of relevancy and accessibility, these were excluded from the model, as they did not make any significant contributions to user evaluation. This might be due to the normal accessibility to the system and information by users, so they do not see any significant differences in this point.

5. Conclusions

This study investigated the impact of information quality on user evaluation of information systems. The study provided a framework solicited from prior research in different information system environments with the aim of building a more inclusive measurement model to both information and system quality. Consisting with previous studies, the study provides some useful conclusions that can be used by managers to structure IS strategies to best benefit their organizations. For example, enhancing information quality can subsequently improve individual performance and result in improved user evaluation as discussed below:

Information quality (IQ) measures are very important as they determine the degree to which information is used. This in turn affects perceived user performance, which sit at the core of the D & M model. Consistent with previous studies in various types of information systems, the results of the current study indicated that the impact of IQ on user evaluation was significant and positive. However, the relationship was not as strong as SQ in term of predicting the variance in user evaluation (DeLone & McLean). Overall, this study proved the importance of IQ as an essential factor influencing positively user evaluation within health information system's environment. These finding support the findings in previous studies and confirmed again the importance of D & M model in predicting user performance.

All IQ measures were analysed to determine the significance of each of the measures and determine which made a significant contributions in predicting user performance. Amongst these measures, completeness, accuracy and timeliness were deemed to be the most important attributes of IQ needed to support users when using the systems to perform tasks. System users give high attention to information completeness as it contributes significantly to their performance. They reported that the completeness of the information available through the systems helps them achieve their performance goals and improves the quality of the work performed. Accuracy also was found to be very important for users, and contributes uniquely to improve user evaluation. It leads to more accurate work with

less mistakes and errors as users rely on the systems to get accurate information needed to perform their tasks and achieve job goals.

To conclude, IQ is associated with high user impacts and evaluation. IQ should be improved in several to increase benefits for users. For example, "by aligning IT strategy with business strategy, using data mining techniques to improve business intelligence, and using data warehousing techniques to aid business decision making. By linking IT strategy with business strategy, information outputs can be designed to provide information that enhances organizational effectiveness (Gorla, Somers, & Wong, 2010, p222). Similarly, data warehousing and data mining techniques provide relevant information (implicit and explicit) to decision makers, which will improve decision making".

National Targets for Romanian Education in the Context of EU Strategy 2020

Dobrotă Carmen – Elena,
Ph.D. student, Romanian Academy – National Institute of Economic Research, Bucharest, Romania,
e-mail: dobrotacarmen@yahoo.com
Marcu Nicu,
professor at University of Bucharest – Faculty of Administration and Business, Bucharest, Romania,
e-mail: marcu.nicu@yahoo.com

Abstract

Since we find ourselves at the middle of the term set for fulfilling targets established for all Member States of the European Union (EU), in the context of the Europe 2020 Strategy, we intend to analyse the current degree of achievement of targets set by Romania in the field of education. We will analyse the actions in the strategic documents relevant for higher education, regarding the 26.7% growth in the share of 30 to 34 year old persons who have attained tertiary education. We shall consider the realism of this target, taking into account the methodology used for determining it and the importance of demographic factors that influence directly and indirectly its achievement. We will also analyse the connection to targets related to the objective of increasing the employment rate. The analysis carried out will substantiate the existence or non-existence of preconditions for reaching the targets assumed by Romania in the field of education, in the remaining interval until 2020.

Keywords: member states, indicators for education, statistical, graduates

Introduction

In order to define the actions required to implement the Europe 2020 Strategy, the European Commission has set a number of five objectives to be reached, by 2020, at European level. These objectives concern employment rate, the financial support for research and development, reducing the effects of climate change, the sustainable use of energy, reducing the rate of early school leaving and increasing the share of tertiary education graduates, as well as measures to counter poverty and social exclusion. In turn, each EU Member State has set its own targets for achieving these objectives, based on economic and institutional realities at national level.

Monitoring the targets for indicators assumed by Romania for the five objectives is achieved through the National Reform Programme (NRP). This constitutes the framework for defining the structural reforms and the development priorities that should guide Romania's evolution until 2020. NRP is updated annually in order to incorporate the priorities set by the Annual Growth Survey, the Employment Guidelines, the Broad Economic Policy Guidelines and other commitments undertaken by Member States within the European Semester (http://ec.europa.eu/europe2020/pdf/csr2015/nrp2015_romania_ro.pdf).
The European Commission, in turn, monitors the progress in achieving national objectives of the Europe 2020 Strategy and includes it in a Country Report, compiled annually. (http://ec.europa.eu/europe2020/pdf/csr2016/cr2016_romania_ro.pdf).

Romania is situated below the EU target of 40% increase in the share of 30 to 34 year old persons who have attained tertiary education with an assumed national target of only 26.7%.

In order to achieve these objectives, Romania has undertaken to implement several measures, estimating the necessary financial resources over three distinct intervals, i.e. 2011-2013, 2014-2015, 2016-2020. The Ministry of National Education and Scientific Research (MNESR) is the Romanian institution responsible for monitoring the measures taken to achieve these two targets in the field of education.

To achieve the goal of increasing to 26.7% the share of 30 to 34 year old persons who have attained tertiary education, Romania has established a series of measures, setting apart those that entail programmes and projects funded from structural and cohesion funds allocated to Romania for 2007-2013, and 2014-2020 respectively. The Ministry responsible has established that structural funds could finance: The 2025 Vision for Tertiary Education project, the finalization of the National Qualifications Framework, the creation of the Single Academic Registry (a database of all students in Romania), a national survey to monitor the insertion of tertiary education graduates into the labour market, supporting doctoral schools and doctoral and postdoctoral scholarships and improving university management. An allocation of approximately 100 million lei was estimated necessary for the achievement of these measures. Other types of measures taken into consideration were: increasing enrolment numbers for undergraduate studies for 2010-2013 by up to 20% and maintaining the result until 2020, reducing the number of study programmes in 2013-2015 and increasing the number of students as well as the operationalization of the National Agency for Student Loans. Their implementation was estimated to be achieved by attracting additional resources from taxes, through an operational tax system for students. (http://www.mae.ro/sites/default/files/file/Europa2021/Memorandum_tinte_nationale.pdf).

The objectives Romania assumed in the field of education are interdependent with that of increasing to 70% the employment rate of the population aged 20 – 64. The synchronization of measures envisaged for achieving these objectives is also necessary. For example, the finalization and operationalization of the National Qualifications Framework in Romania is an essential measure both for increasing the employment rate and for increasing the percentage of tertiary education graduates. Carrying out studies on the correlation between the qualifications provided by the education system and the requirements of the labour market, developing projections of labour market developments and anticipating the needs for skills are measures that take into account both fields, education and employment. (Lucian-Liviu Albu, Petre Caraiani, Mioara Iordan, Perspectivele pieței muncii din România în contextul Strategiei Europa 2020, http://www.cnp.ro/inovatie/docs/seminar-studii-25-06-2012/Rezumat%20studiu%20Piata%20muncii.pdf)

This paper aims to analyse the strategic planning documents, as well as reports and assessments regarding the objectives assumed by Romania in relation to the Europe 2020 Strategy, to analyse the interdependence of actions needed to achieve the objectives, particularly in education, and the factors influencing this. The document analysis is accompanied by statistical data processing and interpretations of results which substantiate the prognosis calculations regarding the achievement of indicators in the field of education by Romania.

Analysis of Relevant Indicators for Education

It is apparent that two of the three definitions of the type of economic growth used in the Europe 2020 Strategy (smart growth and inclusive growth) have education in general and tertiary education in particular as an important determinant. Moreover, of the 7 major initiatives that support the Europe 2020 Strategy, three are related to education / research (Innovation Union, Youth on the Move, Agenda for New Skills and Jobs). It follows that education is one of the fundamental pillars of the Europe 2020 Strategy, not in the sense of mere statistical data, but in that of education which generates knowledge, skills, employability, productivity and ultimately prosperity and which, through its quality and competitiveness, is de facto integrated in the European Higher Education Area (EHEA).

We shall present below the EU image of the three indicators relevant for education, included in the Europe 2020 Strategy.

According to Eurostat, in terms of the percentage of 18 to 24 year old persons who reached a maximum lower secondary level of education (gymnasium/8 school years) and have not participated in any further form of education or training in the total population of the same age, Romania is part of a group of countries which already in 2014 had an overall ratio well above the EU average (11.1%). Along with

Italy, Romania has had an extremely slow pace of improvement in this indicator over the past 10 years. In 2014 compared to 2005, early school leaving was reduced by only 1.5%. If this rhythm were kept constant, the target of 11.3% set for 2020 would seem very difficult to achieve According to the same Eurostat data, in terms of the share of 30 to 34 year old persons who have attained tertiary education, Romania belongs to the group of countries with levels below 30%, along with the Czech Republic, Slovakia and Italy. What makes Romania stand out in this group is the fast pace of growth of this indicator, which tripled in 2014 as compared to 2000. (http://ec.europa.eu/eurostat/web/education-and-training/data/main-tables).

"The substantiation paper for the setting up of national benchmarks for the Europe 2020 Strategy objectives - in the field of education" provided by MNESR states that developments during 2010-2020 regarding the share of 30 to 34 year old persons who have attained tertiary education was based on the evolution of the indicator in the period before 2010 and on the following factors:

Table 1: Values (time series) of influential measures

	2002	2003	2004	2005	2006	2007	2008	2009
Value GDP per capita (in EUP PPS *)	29,4	31,3	34,1	35,0	38,4	41,6	…….	…….
Real growth rate of GDP (%)	5,1	5,2	8,5	4,2	7,9	6,3	7,3	-7,1
Annual public and private expenditure in universities (% of GDP)	0,8	0,6	0,6	1,1	…….	….....	…….	…….
Annual public and private expenditure per student. (EUP PPS*/ GDP per capita)	…….	…….	…….	2375,7 /30,2	…....	……	…….	…….

*EUP PPS - common currency which eliminates differences in price levels across countries, allowing to compare the volume of GDP between countries)

Source: The substantiation paper for the setting up of national benchmarks for the Europe 2020 Strategy objectives - in the field of education, Ministry of National Education and Scientific Research.

However, the forecast issued five years ago had not been elaborated based on regression equations, having the above-mentioned factors as variables, both because of the inconsistency of data series and because of assumptions that should have been formulated about the influencing factors. Moreover, it is not in the least clear what the significance of the determining coefficients of the regression equation would have been and how relevant they would have been. In fact, the forecast system has little sensitivity to such factors but it is strongly influenced by the evolution in the number of graduates and by their age distribution. For example, a 21 years old graduate of 2008 will be found in the 30-34 years old population of 2017 if he should not emigrate in the meantime.

Fully aware of the risks of multifactorial prognosis, it was resorted to analyses of data series on graduates and population, formulating various assumptions on slope coefficients of trend curves. Based on these assumptions, the authors of the substantiation of targets for this indicator have developed three forecast scenarios for the evolution of the Indicator, which are shown in the table below.

Table 2: Forecast scenarios for the share of 30 to 34 year old persons who have attained tertiary education (%)

Scenario	*2010*	*2011*	*2012*	*2013*	*2014*	*2015*	*2016*	*2017*	*2018*	*2019*	*2020*
Optimistic	17,88	19,10	20,51	21,95	23,33	24,57	25,69	26,85	27,92	28,99	29,93
Realistic	17,61	18,41	19,40	20,25	21,30	22,17	23,22	24,06	24,92	25,93	26,74
Pessimistic	17,33	17,89	18,49	19,02	19,65	20,21	20,95	21,73	22,57	23,51	24,60

Note: Forecast issued in 2010. The coloured columns indicate points where the slopes modify. Column 2020 refers to potential targets to reach.
Source: The substantiation paper for the setting up of national benchmarks for the Europe 2020 Strategy objectives - in the field of education, Ministry of National Education and Scientific Research.

Decision makers assumed the value of 26.74% as a target corresponding to the realistic scenario. Romania's progress on this indicator is monitored against this value.
At present, data on the actual evolution of the indicator up to 2014 is available, therefore we can compare this development with the forecast to assess the degree of compliance.

Table 3: The actual development of the indicator "Share of 30 to 34 year old persons who have attained tertiary education" as compared with the forecast (%)

	2010	**2011**	**2012**	**2013**	**2014**

Value published by EUROSTAT	18,30	20,30	21,70	22,90	25,00
Difference (EUROSTAT- Forecast)	0,69	1,89	2,30	2,65	3,70

Source: The substantiation paper for the setting up of national benchmarks for the Europe 2020 Strategy objectives - in the field of education, Ministry of National Education and Scientific Research.

The substantiation paper states that there are differences in methodology, arguing that EUROSTAT takes into account the population with tertiary education, which would create a disadvantage for Romania whose reports include only to the population with university education. The argument is unsubstantiated, since the EUROSTAT methodology takes into account only ISCED levels 5 and 6, which correspond to academic degrees. Post-secondary graduates, although included in the tertiary education, are classified as ISCED 4. Tertiary education consists of post-secondary (ISCED 4) and higher education (ISCED 5-6). The National Institute of Statistics reports to EUROSTAT correctly, according to the methodology, therefore there is no impediment to comparability. The above table shows that, so far, the analysed indicator has had a significantly more favourable evolution than the forecast, which enables us to believe that the level assumed by Romania for 2020 will be exceeded. A more refined analysis of the evolution of the Indicator requires taking into consideration the age distribution of graduates with a bachelor degree, which is why only ISCED 5A and 5B graduates were selected from the Eurostat statistics whose sum corresponds to the NIS reports referring to graduates with a bachelor degree. Eurostat data, ISCED 5A and 5B (cumulative) show that the age range of graduation from undergraduate programs is very large, which means that enrolments in tertiary education were also made at ages much higher than the widely recognized official age (18-19 years). The share of graduates aged between 21 and 25 showed a downward trend from 74% in 2000 to 55% in 2011. Since 2012, the age structure of graduates with a

bachelor degree begins to show a recovery trend. This means that the pool for late enrolment has begun to drain. This trend, which influenced the decrease in enrolments in tertiary education, overlaps with the downward trend in the number of high school graduates with a baccalaureate diploma attending university studies (http://ec.europa.eu/eurostat/web/education-and-training/data/main-tables). Under these circumstances, it is expected that increasingly fewer students will enrol in the Romanian higher education.

The age structure of graduates with a bachelor degree allows for precise calculations to determine the number of people who have attained tertiary education who should be included in any given year in the 30-34 age group. The calculation is illustrated in the diagram below.

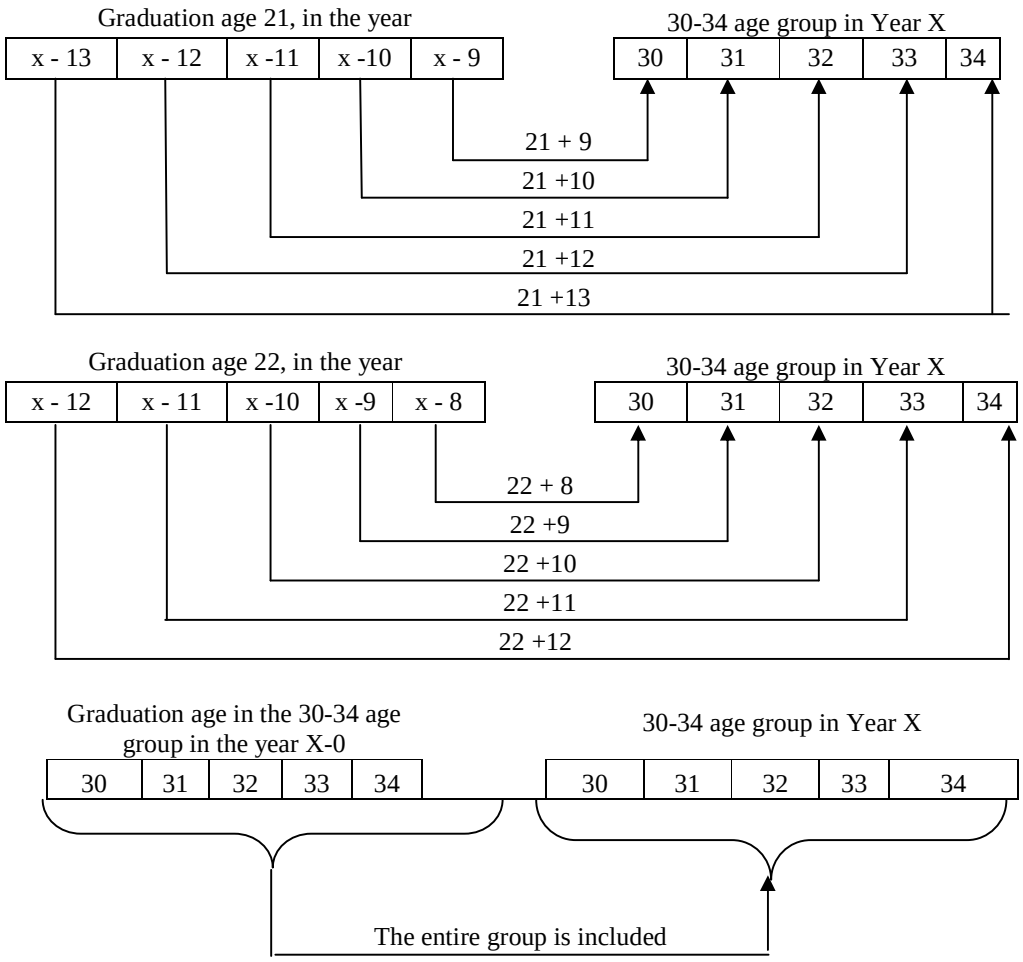

Fig 1. How to determine the number of people who have attained tertiary education who should be included in any given year in the 30-34 age group?

According to these calculations, the number of graduates which ought to be reflected in the 30-34 years old population in the years 2010-2014 is presented in the table below.

Table 4: The number of graduates which ought to be reflected in the 30-34 years old population in the years 2010-2014

	2010	2011	2012	2013	2014
Number of graduates with a bachelor degree aged 30-34	463.904	503.935	535.804	557.129	573.972
Population aged 30-34	1.534.159	1.531.331	1.514.330	1.456.827	1.392.326

Source: For population – EUROSTAT, for graduates - calculation of EUROSTAT data

Knowing the number of graduates with a bachelor degree that should have been included in the 30-34 years old population and the population of this age group, the value of the Indicator "Share of 30 to 34 year old persons who have attained tertiary education" which should have been statistically obtained could be calculated.

Table 5: Calculated value (%) of the Indicator and the value obtained through statistical research

	2010	2011	2012	2013	2014
Calculated value	30,2	32,9	35,4	38,2	41,2
Value obtained through statistical research	18,3	20,3	21,7	22,9	25,0

Source: Calculations based on data in Table 7.5. EUROSTAT for the statistically obtained value

The explanation of the difference resides in the emigration of people who have attained tertiary education in the period between the year of their graduation and the year the statistical research is carried out in order to highlight the status of the Indicator included in the Europe 2020 Strategy. Therefore, in the absence of the phenomenon of emigration of people who have attained tertiary education, Romania would have exceeded since 2014 the 40% target set in the Europe 2020 Strategy for the EU-28 average. This finding highlights the fact that Romania's efforts to school the young population to a tertiary level are largely annihilated by the emigration of highly skilled young people to EU countries. In other words, Romania spends considerable amounts of public and private resources for superior level schooling but the benefits of these financial efforts are externalized. In this context, Romania "subsidizes" the higher qualification of the European workforce.
In order to get an accurate picture of losses concerning the population who attained tertiary education, the absolute values must be highlighted. The results are shown in the table below, illustrating the young persons who had attained tertiary education and emigrated in the period between graduation and 2010-2014.

Table 6: The young persons who had attained tertiary education and emigrated in the period between graduation and 2010-2014 (no. of persons)

	2010	2011	2012	2013	2014
Graduates who should have been found in the population aged 30-34	463.904	503.935	535.804	557.129	573.972
Graduates who can be found in the population aged 30-34	281.000	310.300	325.500	329.900	343.600
Emigrations in the period between graduation and the mentioned years	182.904	193.635	210.304	227.229	230.372

Source: Calculations based on data published by EUROSTAT

Since 1997 (the first year taken into account in determining the number of graduates who should have been found in the population aged 30-34) until 2014, about 230 thousand people who had attained tertiary education left the country (the number of deaths has an insignificant influence for this age group).
According to the above, it follows that one of the key factors influencing the progress of the indicator "Share of 30 to 34 year old persons who have attained tertiary education" is emigration. Unfortunately, this factor was not taken into account for the substantiation of the target Romania assumed for 2020. If this factor had been taken into account, it would, in turn, have influenced the substantiation of enrolment numbers and, as a consequence, the public funding of tertiary education. However, the consequence can be the maintenance of an oversized tertiary education system, whose quality cannot be precisely assessed and whose responsiveness to the socio-economic needs of Romania is still not the desired one.
In forecast, the evolution of the Indicator if the emigration of young people with tertiary education had not occurred, would have been the one illustrated in the table below.

Table 7: Evolution of "Share of 30 to 34 year old persons who have attained tertiary education "during 2015-2020 (thousands persons)

	2015	2016	2017	2018	2019	2020
Number of graduates who should have been found in the population aged 30-34	584	612	606	606	590	560
Population aged 30-34	1.336	1.305	1.303	1.334	1.382	1.405
Share of 30 to 34 year old persons who have attained tertiary education in the total 30 to 34 year old population (%)	43,7	46,9	46,5	45,4	42,7	39,8

Source: Calculations based on data published by EUROSTAT. For population, the EUROSTAT forecast was used (the low fertility scenario)

The analysed indicator continues to grow until 2016, when it peaks at 46.9%. This level is achieved both due to the increasing number of tertiary education graduates and as a result of the decrease in population aged 30-34. Starting in 2017 the number of graduates with a bachelor diploma that reach the age of 30-34 begins to decline (the decrease in the number of enrolments in tertiary education starts to propagate), and the population in the 30-34 age group begins to increase slightly (according to the EUROSTAT forecast) (http://ec.europa.eu/eurostat/web/education-and-training/data/main-tables). The combined effect of these two trends is the relatively rapid decrease in the levels of the analysed indicator, which reaches 39.8% in 2020. If the trends remain valid, the achievable levels of the Indicator will depend on the levels of the emigration. Since there are no statistics on the emigration of people with tertiary education after graduation, a number of assumptions to define scenarios have to be formulated. For forecasting purposes, two scenarios shall be adopted. In Scenario 1, the volume of emigration of young people with tertiary education (cumulatively, starting with the year of graduation), which amounts to 230 thousand people, will decrease by an annual average of 10 thousand people as a result of sliding the calculation period to the right. This means that the strong migration of 2001 will sensibly reduce its influence, and the one started in 2007 will have an increasingly reduced but still quite consistent effect. A second assumption envisages that annual emigration on the forecast interval will be virtually zero. Regarding Scenario 2, the first assumption in Scenario 1 is maintained, but it is assumed that the annual average emigration over the forecast interval will amount to 5000 persons with tertiary education.

Values calculated over the forecast interval of the Indicator "Share of 30 to 34 year old persons who have attained tertiary education" are presented in the following table.

Table 8: Evolution of the indicator "Share of 30 to 34 year old persons who have attained tertiary education" for the period 2015- 2020

	2015	2016	2017	2018	2019	2020
Number of graduates who should have been found in the population aged 30-34 (thousand pers.)	584	612	606	606	590	560
Population aged 30-34 according to the EUROSTAT low fertility hypothesis (thousand pers.)	1.336	1.305	1.303	1.334	1.382	1.405
Emigration according to Scenario 1 (thousand pers.)	220	210	200	190	180	170
Emigration according to Scenario 2 (thousand pers.)	225	215	205	195	185	175
Value of the Indicator (%): Scenario 1	27,2	30,8	31,2	31,2	29,6	**27,8**
Value of the Indicator (%): Scenario 2	26,8	30,4	30,8	30,8	29,3	**26,7**

According to the above forecast, it is expected that in the next five years the analysed indicator reach values above the target assumed by Romania in the Europe 2020 Strategy. This growth, visible since 2014, is due to the massive enrolments in the 2005/2006 - 2009/2010 academic years. Starting in 2019 the indicator value will begin to decline.

Undoubtedly, there is a correlation between education attainment and employability (employment). People with low educational level are the most vulnerable, i.e. the population who does not go beyond lower-secondary education. Regarding the indicator on the employment rate of the population aged 20-64, Romania has an employment rate of 65.7%, the target for 2020 being 70%. The population with secondary (high school) and post-secondary (post-high school) levels of education have higher employment levels, but these levels vary widely from country to country. Although the population with tertiary education has the highest employment level, in the case of emerging countries this should be looked at more closely because it can hide phenomena related to internal and external mobility. Highly qualified workforce, when in excess, can migrate internally to jobs that could otherwise be filled by people with secondary qualifications, and also abroad, in which case they may accept lower qualification jobs. For emerging countries, among which Romania, negative migration flows act as regulators of employment rates (not only for people with tertiary education), but can also induce destructurations. For example, the emigration of doctors causes major disturbances in the functioning of the public health system in Romania.

The Demographic Evolution of Romania and its Implications on Achieving Targets Assumed under the Europe 2020 Strategy

According to Eurostat sources, during 1990-2015, Romania's population decreased by 3.35 million. The main causes of this demographic decline were the declining birth rate and the negative balance of external migration flows (immigration - emigration). Between 1990-2014, Romania's population decreased by 923 thousands inhabitants. The difference of 2.4 million, to the total loss of 3.35 million, is due to the net negative balance of external migration flows (http://ec.europa.eu/eurostat/web/population-demography-migration-projections/population-projections-data). Moreover, the decline in economic activity and the lower living standard have transformed Romania into a country of emigration. EU accession has brought, among other things, the free movement of persons, which facilitated migration in Europe. The main share of Romanian emigration is represented by the economically active population, aged 20-59 (79.4% in

2013), within which the young population aged 20-39 represents 68.0%). (INS, Anuarul Statistic al României 2015 - data series, http://www.insse.ro/cms/files/arhiva_buletine2015/bsl_11.pdf).

A synthetic image of the evolutions during 1990-2015 of the pre-university school-age population is shown in the following table.

Table 9: Losses of school age population on age groups up to and after the year of relative stabilization of evolution

Age group	***Losses up to stabilization year as compared to 1990 (%)***	***School-age population (thousand persons)***						***Losses up to 2015 as compared to stabilization year (%)***
		1990	***1995***	***2000***	***2005***	***2010***	***2015***	
0-4	*29,3*	***1.811,4***	***1.280,7***	*1.144,7*	*1.090,9*	*1.051,7*	***953,3***	***25,5***
5-9	*26,3*	***1.720,3***	***Major migration flows***	***1.268,5***	*1.129,8*	*1.056,6*	***1.052,6***	***14,6***
10-14	*44,5*	***1.976,8***			***x***	***1.097,7***	***1.052,5***	***4,1***
15-19	*40,4*	***1.894,6***				***1.128,7***	***1.092,4***	***3,2***

Source: Calculated based on EUROSTAT

The table above highlights the levels of school-age population which were the baseline in 1990, the losses due to major migration flows (the shocks in 1991, 2001 and 2007), the sliding across generations and the levels of relative stabilization reached in 2015.

It is apparent that the levels of school-age population at which the process became relatively stable in 2015 are almost a half of those in 1990. If in the following period there should be no new resurgence of migration flows, the school-age population corresponding to primary and secondary educational levels will mostly remain below the influence of the birth rate. The demographic process has settled at a significantly lower level. The consequence is the rescaling of primary and secondary education. If in 1990 the system included 1.8 - 1.9 million students, the current numbers barely rise above a million. The concentration of the education system is no longer a policy option, but an imperative of demographic realities.

The 20-24 age group, corresponding to tertiary education, hadn't witnessed until 2005 large losses as compared to the 1990 baseline. In 2000, the loss compared to the entire 10-14 year old population of 1990 was of only 14 thousand people, and by 2005 the loss of 5-9 years old population as compared to the baseline was of around 50 thousand people. The large numbers of students in 1990 and the relatively small losses along the way until 2005 generated a benefit for the tertiary education, as a support to its expansion, in terms of large populations aged 20-24. The first significant drop in population in this age group is only visible in 2010 and it is due to the massive emigration in 2007 and the following years, a consequence of Romania's accession to the EU. After 2010, the decline in population in the 20-24 age group is increasing due to the propagation of the decline in population aged 0-4 started in 1991, through migration and lower birth rate.

Repeating through successive generations the propagation mechanism of the evolution of the 0-4 age group, while adding the 20-24 age group corresponding to tertiary education, it becomes apparent that the population aged 20-24 will evolve over the coming decades in a descending manner, albeit starting from a baseline lower than in 1990 by almost 800 thousand persons, as can be seen from the table below.

Table 10: The loss of population aged 20-24 due to the propagation effect of the decline in 0-4 years old population (thousand pers.)

Age group	*1990*	*1995*	*2000*	*2005*	*2010*	*2015*
0-4	***1.811,4***	***1.280,7***	*1144,7*	*1.090,9*	*1.051,7*	*953,3*
5-9	*1.720,3*		***1.268,5***	*1.129,8*	*1.056,6*	*1.052,6*
10-14	*1.976,8*			***?***	*1.097,7*	*1.052,5*
15-19	*1.894,6*				***1.128,7***	*1.092,4*
20-24	*1.908,4*					***1.191,7***

Source: Calculated based on EUROSTAT

In summary, in the 25 years examined, young population aged 0-24 has decreased by 4 million, which means it currently represents a mere 26.9% of the country's population while in 1990 its share was 40.1%. In decades to come, this decline in the young population will impact the active population from an economical perspective and, therefore, the country's economic potential.

The contraction of pre-university education system is not a subjective political option, but an imperative of demographic realities. Thus, the population in the 0-19 age group was reduced by 3.3 million during 1990-2015 and, for the 2015-2040 period, the foreseen reduction is of almost 0.7 million people. The pre-university education levels have been facing for years a situation in which school-age population is only a half of the one in 1990.

The shock wave of the radical decrease in school population for the 0-4, 5-9, 10-14 and 15-19 age groups has propagated, since 2010, to the 20-24 years old population corresponding to tertiary education. According to Eurostat forecast, the population in the 20-64 age group will decrease by 2 million in 2040 as compared to 2015 (http://ec.europa.eu/eurostat/web/population-demography-migration-projections/population-projections-data). In this scenario, numbers such as the 907,353 students enrolled in tertiary education in the academic year 2007/2008 will no longer be possible. Even figures such as the 433,234 people enrolled in the 2013/2014 academic year will remain a memory. Fierce competition on the market for tertiary education will force universities to reform and improve the quality of educational services provided.

Conclusive Remarks

"The share of 30 to 34 year old persons who have attained tertiary education" is not a stand apart indicator, which can be separated from the context in which it was defined – the Europe 2020 Strategy. Tertiary education is a factor which supports smart, sustainable and inclusive economic growth. In order to fulfil this role, tertiary education must be high-quality, competitive in a global market and adapted to

the socio-economic needs. Unless these conditions are met, the Indicator remains a simple statistical report, lacking relevance, which simply counts the number of university diplomas among the 30-34 years old population.

The levels of the analysed Indicator were substantially influenced by the emigration of young people with tertiary education. If it had not been for this emigration, Romania would have exceeded, ever since 2014, the 40% target set by the Europe 2020 Strategy for the EU-28 average to be achieved by 2020. In other words, Romania's efforts to school young people to a higher level are largely annihilated by this emigration, the result being that costs of training are internalized while its benefits are externalized. This phenomenon must be taken into account in formulating funding policies.

During the 2015-2020 period, according to forecasts, the Indicator assumed in the Europe 2020 Strategy will be higher than the assumed target of 26.7%. After 2020, the Indicator will assume a downward trend leading to values lower than the target, due to lower number of registrations in tertiary education. The only route to recovery is a significant improvement in the quality of tertiary education and an increasingly active participation in the international students' market.

Study Concerning the Per-Household Revenue and the Food Expenses in Giurgiu County - Romania

Denisa Florentina Burcea[1]
[1] Faculty of Management, Economic Engineering in Agriculture and Rural Development, University of Agronomic Sciences and Veterinary Medicine of Bucharest, 59 Marasti Blvd, District 1, Bucharest, Romania
Corresponding author email: burceadenisa@gmail.com

Abstract:

The paper is written based on a survey conducted in 2015 in the Macro-Region 3, specifically in Giurgiu county, one of the seven counties of the South-Muntenia Region. The level of population's revenue, together with the level of per household expenses on food and beverages are very important indicators of the way the economic stability is being assured on regional and national level. This paper has the main purpose to analyse the level of food expenses in the Giurgu county, correlated with the per-household revenue that those interrogated replied having. I used the method of the questionnaire of research in 12 villages and Giurgiu municipality. The results led to the conclusion that Giurgiu households have a lower income then average national level, but they also spend less money on food then the national average. Also, the largest part of the expenses made go on services, with urban households spending slightly more on services then the rural households.

Keywords: Giurgiu, expenses, food expenditure, revenue,

Introduction

This paper is based on the results of a survey conducted in June-July 2015, on 272 people from Giurgiu county. The area of research was Giurgiu county, one of the seven counties of the South-Muntenia region, part of the Macro-Region 3 of Romania.

The target population was represented by all the persons from the general population in urban and rural areas, over 18 years of age, with the observance of the official proportions of the target population in terms of respondents' gender.

The study was conducted in the idea that the population of Giurgiu county is consuming more cereals, roots and tubers than the national average, due to lower incomes per households. Also I was assuming that a big part of the per-household revenue (or the income per household) is being spent on food and beverages.

The main purpose of a national economy is for the population to have at least the necessary amount of money to ensure its own consumption, but also a great percentage of the population should be able to save part of their revenue, after spending their salary on all the strictly necessary items and services. According to M. S. Stănculescu, Romania did not concentrate too much on the problem of poverty and inequality of its population until 1994 (Stănculescu, 2009). This lack of interest concerning this matter may be due to a long lasting relationship of equilibrium between revenue and expenditure in Romania, demonstrated by Stoian in 2008 (Stoian, 2008) and also by Hye and Jalil in 2010 (Hye, Jalil, 2010)

Unfortunately, in Giurgiu county, as well as in all the counties in Romania that are preponderantly rural, very few families are able to put money aside from their incomes and when that happens the amount is quite small.

Materials and Methods

In the investigation we used the questionnaire of research method, the questionnaire being structured by using the panel technique (funnelling) (Septimiu Chelcea, 2007). Before framing the questionnaire I created a number of assumptions that were either confirmed or denied during the investigation.
The study used a probabilistic, multi-layered sampling model. Following the stratifications made the survey was conducted in 12 rural settlements (182 questionnaires) and Giurgiu municipality (90 questionnaires). The 12 settlements selected were: Gogoşari, Gostinu, Toporu, Stăneşti, Vedea, Oinacu, Clejani, Ogrezeni, Băneasa, Frăteşti, Ghimpaţi, Roata de Jos. For the respondents selection inside the localities I used the random path method.

The results of the survey conducted in Giurgiu county were introduced and then processed using IBM SPSS Statistics, version 20. With this program there were carried out a series of correlations between different variables extracted from the questionnaire, including the correlation between the income levels and the consumption of cereals, tubers and roots.

Data on the development of revenue and expenditure at the national, macro-regional and regional levels were gathered and processed from the INS database -Tempo Online.

Results and Discussions

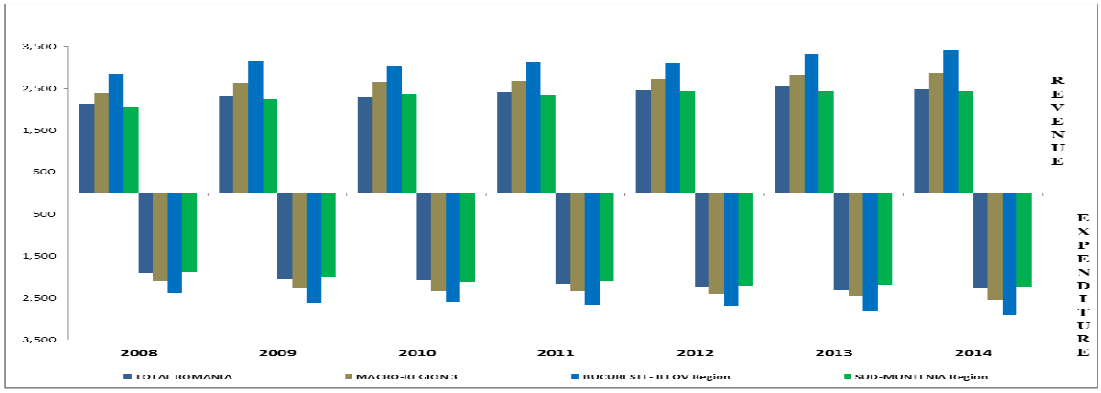
Monthly average incomes and expenses per household:

The monthly average incomes achieved in Macro-Region 3 are located generally for the analyzed period, between 2,394.66 RON in 2008 and 2,875.24 RON in 2014. Compared to the monthly average incomes at the country level, households from Macro-Region 3 earned in 2014 eg with 374.52 RON, respectively with 14.98% more. At regional level, South-Muntenia Region households earned on average in the analyzed period, between 2,059.45 RON in 2008 and 2,442.60 RON in 2014. As a difference to the incomes in the Macro - Region, on average, households in South - MUNTENIA Region won in 2014 with 43.64 RON respectively with 15.05% less than the Macro – Region's average. However, in the Bucureşti - Ilfov Region revenues were with 544.93 RON, respectively with 18.95% higher than the Macro – Region's average.

The monthly average expenses in the Macro-Region 3 ranged between 2,102.02 RON in 2008 and 2,535.96 RON in 2014. In 2014 they were with 11.75% and 266.71 RON higher than the national average. In South-Muntenia Region the spending were on average of 1,889.46 RON in 2008 and 2,240.33 RON in 2014. In 2014 they were with 11.66% lower than the Macro – Region's average. Instead, in the Bucureştit-Ilfov Region spending were in the analyzed period by more than 11% higher than the macro-regional level, for example being in 2014 with 11.75% higher.

It is noted that the monthly average per-household revenue increased gradually at both the Macro – Region's level and the component regions level. But the expenditures have the same growth rate. For example, in the Macro-Region 3, the per-household incomes in 2014 were with 20.07% higher than in 2008, while the expenses also rose by 20.64%, the difference between these two growth rates being of 0.57 percentage points. In the South-Muntenia region incomes increased in 2014 compared to 2008 with 18.60%, while expenses increased by 18.57%. The income growth was with only 0.03 percentage points higher than the increase in expenses.

In the Bucureşti-Ilfov Region, despite revenue being much higher than the average incomes in South-Muntenia Region, the expenses are higher also. If in 2008 a household in the Bucureşti-Ilfov Region earned with 38.17% more than a household in the South-Muntenia Region and spent with 26.38% more, in 2014 the incomes came to be with 40.02% higher, while spending increased also, being with 29.82% higher than the average expenditure of a household in the South-Muntenia Region. We can notice however that the revenues of a household from Bucharest-Ilfov rose by 20.20% during the reviewed period, while expenditure increased by 21.79%, with 1.59 percentage points more than the revenues.



Source: Original, after data provided by INS – TEMPO Online

Graph 1.: Monthly average revenue and expenditure per household (lei RON)

Moreover, we can see from Table 1 that in general in the country, revenues are with over 10% greater than expenses. The percentage difference between revenues and expenditures is higher in the Macro-Region 3 due to higher revenue of the Bucharest-Ilfov inhabitants. It is noted that in this last region mentioned the revenue per household is with over 16% higher than the expenditures. In the South-Muntenia Region, however, the difference between revenues and expenditures is generally below the country level average and even below the Macro – Region's average.

Table 1.: Difference percentages between Revenue and Expenditure

	2008	**2009**	**2010**	**2011**	**2012**	**2013**	**2014**
	MU: %						
Romania	11.30	13.12	11.70	10.69	10.27	10.43	10.20
Macro- Region 3	13.92	16.00	14.26	14.58	13.08	14.53	13.38
Bucureşti – Ilfov Region	19.16	20.31	16.99	17.46	16.17	18.10	17.60

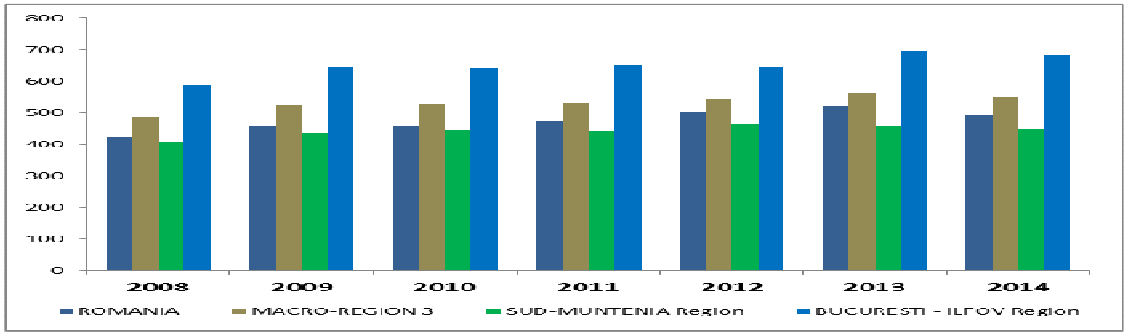
Source: Original, after data provided by INS – TEMPO Online

Expenses for food and beverages:

Of the total expenditure of a household, the most important expenses are those related to food. Therefore this indicator provides information on the share of food expenditures of total expenditures. In the Macro-Region 3 it is noted that these expenses are higher than country's average. The biggest difference was recorded in 2010 when they were by 16.10% higher than the national average. As a share of the total expenses that a household has food and drinks expenses in the Macro-Region 3 ranged between 23.10% in 2008 and 21.75% in 2009 and 2014. Although the amount steadily increased as value, the proportion of food expenses out of total expenditure decreased during the analyzed period.

In South-Muntenia Region, spending on food accounted for between 21.66% in 2008 and 19.92% in 2014, out of the total expenditure per household. In this case there is a downward trend, the share of food expenditure in total expenditure declining by 8.29% in 2014 compared to 2008. However,

households in South-Muntenia Region are spending less on food than there are spending on average households nationally. The biggest difference was recorded in 2013 when a household from South-Muntenia spent on food by 11.81% less than the average household in the country. As for the Macro-Region 3, less is spent, the maximum difference being in 2014, when the expenses per household were by 19.09% smaller than in the South-Muntenia Region.

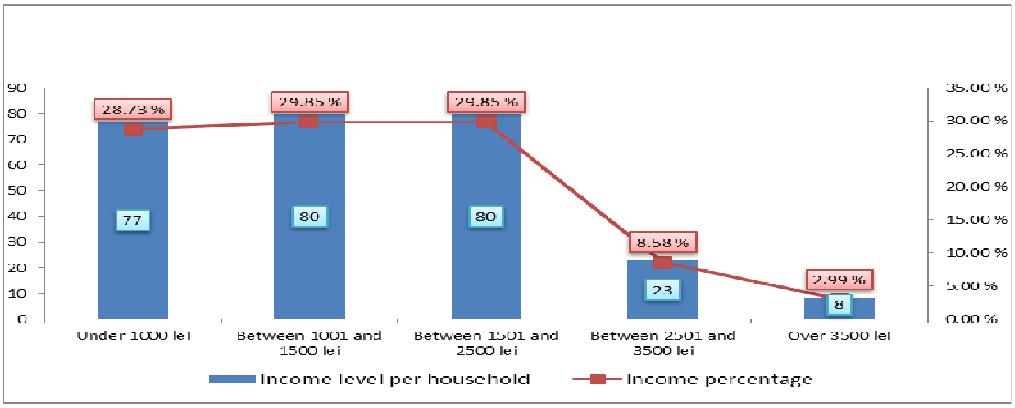


Source: Original, after data provided by INS – TEMPO Online

Graph 2.: Expenses for food and beverages consumed (lei RON)

The assumptions based on which I started compiling this inquiry related to the food security of the Giurgiu county's population were in number of 9 and the ones related to the households incomes and spendings are:
Assumption 6: It is assumed that there is an inverse correlation between the revenues and the consumption of cereals, roots and tubers, meaning that the higher the household income is, the lower the consumption of cereals, roots and tubers is.
Assumption 9: Over 35% of the household expenditures are allocated to food expenses.

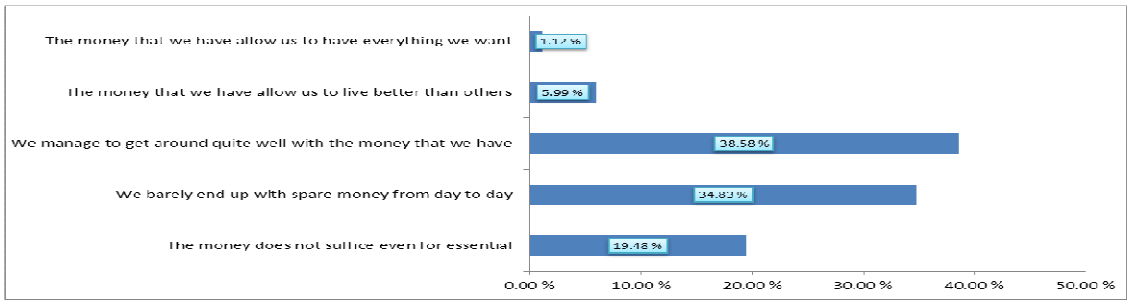
Of the 268 people who responded to the question about the household income, only 31 people or 11.57% answered that household incomes exceed 2,500 RON. We notice that the great majority of the respondents, over 55% of total respondents have a per-household revenue of under 1,500 RON.



Source: Original

Graph 3.: Income level per household

Moreover, much of the population hardly copes with the amounts of money they held at the household level, only a percentage of 1.12% of the respondents believing that they can afford to buy everything they want with the revenue of the household.



Source: Original

Graph 4.: Income level framing mode

To find an answer to Assumption 6, I realized a correlation table in SPSS between the obtained revenue per household and the daily consumption of potatoes, carrots and cereals. From the table we can see that there is a strong correlation between the household income and the consumption of potatoes, which is inversely correlated (r = -0.142 and P-value = 0.024 <0.05). Also, between eating carrots and root vegetables and the household income is a strong, inverse correlation (r = -0.200 and P-value = 0.001 <0.05). These inverse correlations signify that the more the household income increases, the consumption of potatoes, carrots and root vegetables decreases, which partially confirms the Assumption 6.

But as regarding the consumption of cereals we can say that there is also a strong inverse correlation between the consumption of cereals and revenues per household (r = -0.116), but this time there are insufficient data to consider this correlation as being significant (p-value = 0.063 > 0.05).

So we come to the conclusion that ***the assumption 6 is partially confirmed, only in the case of the potatoes, carrots and root vegetables consumption and not in the case of cereals and other cereal products.*** To consider the correlation between the consumption of cereals and the household incomes as a significant one, more data are needed.

Table 2.: Correlation table between Income per household and Potatoes daily consumption, Carrots and other root vegetables daily consumption, Cereals and other cereal products daily consumption

Correlations					
		The monthly net income per household	Potatoes	Carrots and other root vegetables	Cereals and other cereal products
The monthly net income per household	Pearson Correlation	1	-.142*	-.200**	-.116
	Sig. (2-tailed)		.024	.001	.063
	N	268	256	256	258
Potatoes	Pearson Correlation	-.142*	1	.633**	.047
	Sig. (2-tailed)	.024		.000	.458

	N	258	250	250	261

Source: Original

> Nationally, in 2007-2013, the highest share of monthly expenditure was for the food expenses. In addition, between 2007 and 2013 occurred an increase in the share of this type of expenditures, from 35.8% to 36.2%, by 0.4 p.p. more. (Burcea D., Dona I., 2015)

The assumption made was that in Giurgiu county the food expenditure share is close to the value at national level

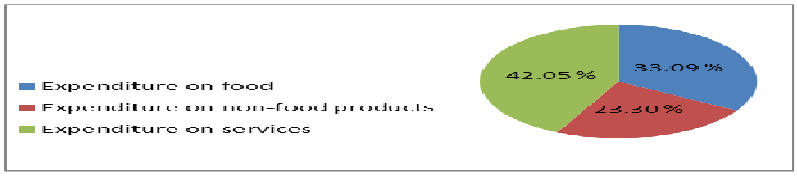
From graph 5 we can say that on average, the surveyed households spend 33.09% on food, below the average food expenditure per country. The largest share is related to services, 42.05%.

Broken down by residence, there is a percentage by 2.78 p.p. greater (8.69%) for spending on food in urban areas than in rural ones. Besides, the lowest food expenditure share was 10% of total expenditure for 11 respondents (4% of total respondents), all from the rural areas.

In both cases expenses on services are predominant, but the value is greater still for the urban households.

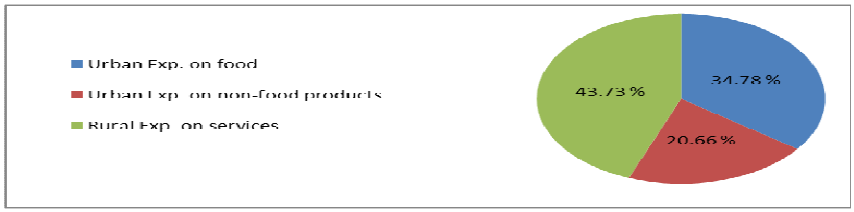
From the data obtained it can be concluded that in urban areas in Giurgiu county the food expenditure are by 8.69% larger than in the countryside, which is normal because in rural areas much of the consumption is met from their own farms. But at the same time urban residents are spending on services such as cable TV, internet, telephone, electricity, gas, maintenance, transport, health, education, hospitality, etc., by 6.37% more than those in rural areas. This difference is understandable, in light of the absence of certain charges in rural areas. In general, households in the Romanian villages and in Giurgiu county don't have certain expenditure such as: housing administration and maintenance expenses, local transportation and in some cases, internet, gas and HORECA (Hotels, Restaurants, Coffee Shops)

Thus ***the Assumption 9*** which states that household food expenditure represents the largest share of the total expenditure, with values above 35%, ***is ruled out***.



Source: Original

Graph 5.: Average share of consumption expenditure from total household queried



Source: Original

Graph 6.: Average share of consumption expenditure in urban areas

Source: Original

Graph 7.: Average share of consumption expenditure in rural areas

Conclusions

The monthly average per-household revenue for Romania were in 2014 around 2,500 RON, while the monthly average expenditure were in 2014 approximately 2,270 RON. The share of food expenses out of total expenditure was in 2014 of 36.2%. The average household revenues of the surveyed population in Giurgiu county are between 1,501 RON and 2,500 RON, with an average expenditure on food of 33.09%. Against this fact, a great percentage of those questioned think that they can manage with their per-household revenues.

In South-Muntenia Region the incomes don't exceed with much the expenses, being in 2014 by only 9.03% bigger than the spending.

We can conclude that the average income per household is lower in Giurgiu county than at national level, but at the same time, the share of food expenditure out of total expenditure is smaller, due to the fact that most of the population lives in villages and a great part of their food consumption is from their own household.

Also, against expectations, Giurgiu citizens spend more on services, the population in towns spending with 2.62 p.p. more than those living in rural areas.

The Biotech Industry – A Challenge of Intelligent Business

Cristescu Lavinia-Alexandra, The Bucharest University of Economic Studies, Faculty of Business and Tourism, Bucharest, Romania, cristescu.lavinia@yahoo.com

Abstract

In the context of present economy, the sustainability of the biotech business is being questioned. Therefore, this paper aims to identify three key aspects: the consumer's perspective upon GM products, the perspective of the multinational companies involved in the biotech industry and the impact of the economic crisis in the sustainability of their business, profits and costs.
The purpose of this study is to point out if the GMO business adds value to an economy affected by the crisis and if all this industry's challenges are leading towards a more intelligent economy.
The methods used in this research consist of the following: a database of the multinational companies from the biotech industry and their revenue; a business model for these companies, and an exploratory research based on a questionnaire to show the consumer's perspective upon GMO's.
The paper shows the results and interpretation of the questionnaire, the advantages of the proposed business model for the biotech companies, as well as their revenue results from the database.
In conclusion, GMO based products contribute to high progress in business towards an intelligent economy. The biotech industry managed to keep being sustainable in spite all contradictions.

Keywords: business, model ,biotechnology, genetically modified products, innovation, sustainability

Introduction

The impact of business sustainability in the biotechnology industry has started in the late 2008, when like the rest of the global economy, this industry had to face a lot of challenges concerning the viability of its business and financing model. In this context, the purpose of this study is to point out if the biotech business adds value to present economic challenges and leading towards a more intelligent economy.The second objective of the research it to identify, the perspective of the multinational companies involved in the biotech industry and the sustainability of their business, profits and costs. The present research also aims to identify the consumer's perspective upon GM products.

Therefore, the research is structured into three main parts as following: identifying the economic context of the biotech business, this industry's overview; a case study presenting the impact of economic crisis on biotech companies' business sustainability and the results of an exploratory study on a sample of availability concerning GMO's.

The research methodology consists of the above mentioned Case Study that contains identified and interpreted results of core financial indicators and business models belonging to three strong multinational companies involved in the biotech industry such as Monsanto, Syngenta and Bayer Crop Science. Last but not least, the research methodology is completed by a questionnaire based research and statistical data retrieved from the scientific materials.

1.The Economic Context of the Biotech Business: Industry

Many countries from all over the world have long been dedicating resources to supporting the growth of local biotechnology industries, investing billions of dollars and offering generous tax abatements demanding in return to witness the significant societal and economic benefits of biotechnology product development and merchandising.

Whereas in times of relative economic sustainability there may be support to dedicate resources for future returns, in the face of an economic crisis difficult resource-allocation decisions must be made,

and it is questionable how committed governments and their constituents will be for investing in biotechnology development initiatives. Given nowadays economic scenario the governments have to decide if biotechnology support levels are maintained, increased or withdrawn, and if supportive mechanisms are redesigned to change focus on local investment by strong foreign firms vs. domestic entrepreneurial growth. The biotechnology industry has always faced dynamic challenges. From bans on genetically modified crops, GMO product labeling and questions about the very patentability of biotechnology products, the commercialization of biotechnology has always been in the loop. However, strong companies and their business models have persevered over time, managing to overcome the challenges of the biotech and GMO industry, leading towards a more intelligent economy. The success of biotech companies is based on business strategies that focus on innovation, research and development and presence on foreign markets. The companies involved in this business mix these key elements in the effort to put the crisis behind them.

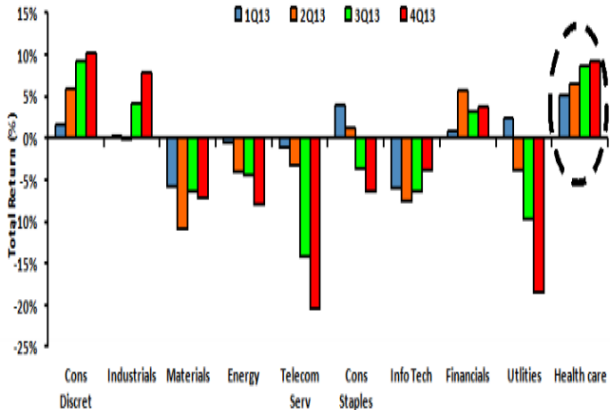

Fig 1: Return on investment from the healthcare sector

Source: J.P. Morgan, 2014 Global Biotech Outlook, https://www.jpmorgan.com/global/insights/healthcare accessed at 01.02.2016

Standard & Poor's Financial Services LLC (S&P) is an American financial services company that publishes financial research and analysis on stocks and bonds. Therefore in the S&P 500 subsectors analyzed in the four quarters of 2013, the top 3 performing sectors were Discretionary, Healthcare (which includes the biotech industry) and Industrial, while Telecom and Utilities finished with a single-digit return. According to S&P, Healthcare has outperformed the broader markets over the past 3 years. Notably in the figure, there are still two sectors that are more expensive than Healthcare: Telecom and Utilities. Healthcare outperformed the S&P 500 throughout 2013, with the relative outperformance increasing every quarter (see Figure 1).

2. Case Study – The Impact of Present Economy on Biotech Companies Business Sustainability

This case study aims to identify and interpret the results of the core financial indicators and business models of three strong multinational companies involved in the biotech industry such as Monsanto, Syngenta and Bayer Crop Science and the impact of present economy in the sustainability of their business. Monsanto Co. (headquartered in USA) provides agricultural products for farmers. Its seeds, biotechnology trait products, and herbicides provide farmers with solutions that improve productivity and produce better foods for consumers and better feed for animals. The company operates its business through two segments: Seeds & Genomics and Agricultural Productivity. The Seeds & Genomics segment produces seed brands, including DEKALB, Asgrow, Deltapine, Seminis, and De Ruiter and develops biotechnology traits that assist farmers in controlling insects and weeds. The Agricultural Productivity segment manufactures Roundup and Harness brand herbicides and other herbicides. It also provides other seed companies with genetic material and biotechnology traits for their seed brands. In 2015 Monsanto ranked #34 in the Forbes Top of World's Most Innovative

Companies. Monsanto's business model focuses on productivity: increasing the tons of crop that can be produced per hour of labor and/or per acre of land.

It is the company's belief that increasing yield potential is about a total system working together in partnership with the grower to drive yield in a sustainable way by combining solutions such as: biotechnology, plant breeding, biological, crop protection and agronomic practices.

Fig 2: Combined Solutions for increasing yield potential

Source: Research and Development Pipeline Brochure – Monsanto; http://www.monsanto.com/products/documents/pipeline-brochures/2014-rd-pipeline-brochure.pdf

According to Monsanto's innovations in the biotech field, the business adds value to an economy affected by the crisis by creating technological revolutions such as seed chippers, that enable researchers to know what characteristics plants will have before the seed is even planted. This helps the company to get the best seeds to farmers faster. Advances in plant breeding are helping increase the rate of improvement in key plant characteristics, such as grain yield and disease tolerance. Also, investments in agricultural solutions are designing new methods to unlock yield potential in the case of corn, soybean, cotton, canola, sugarcane, wheat, vegetables. Also, the company produces Integrated Farming Systems that combine advanced seed genetics, on-farm agronomic practices and IT innovations to drive yield. Farmers evaluate many types of information each season, and can take advantage of state-of-the-art technology for recommendations.

Bayer AG (headquartered in Germany) is engaged in the development, manufacture and distribution of products in the areas of health care, nutrition and high-tech materials. It operates through the Healthcare, Crop Science and Material Science subgroups, which are supported by three service companies. The CropScience subgroup consists of two operating segments: Crop Protection / BioScience and Environmental Science. The Crop Protection segment includes herbicides, fungicides, insecticides and seed treatment units, while BioScience focuses on seeds and plant traits. The Environmental segment offers non-agricultural pest and weed control products. The MaterialScience subgroup develops, manufactures and distributes high-performance products in the areas of polyurethanes, polycarbonates, coating and adhesive raw materials, and functional films.

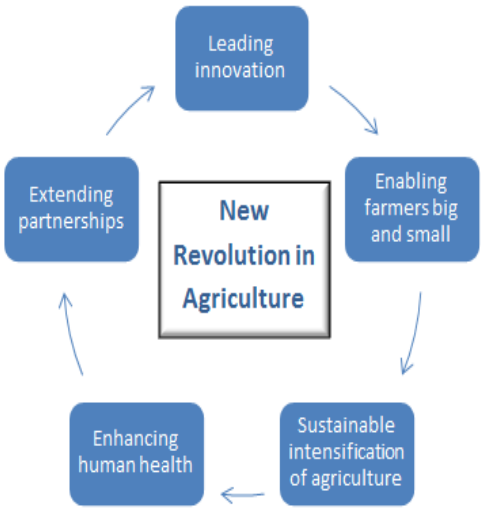

Fig 3: Point plan revolution in agriculture

Source: own research based on http://www.cropscience.bayer.com/Commitment/New-Revolution-in-Agriculture.aspx

Bayer's Crop Science business model focuses on a five-point-plan to bring about a New Revolution in Agriculture.

Leading innovation, enabling farmers big and small, driving a sustainable intensification of agriculture, enhancing human health, extending partnerships; having the belief that a significant and sustainable increase in agricultural production worldwide is urgently needed. Syngenta AG (headquartered in Switzerland) is engaged in the manufacture, development, and distribution of crop protection products and seeds. It operates through the following geographical segments: Europe, Africa and Middle East; North America; Latin America; Asia Pacific; and Lawn and Garden. The four geographic regions comprise the integrated crop protection and seeds business. The Crop Protection business includes herbicides, insecticides, fungicides, and seed treatments. The Seeds business operates in the high value commercial sector of field crops and vegetables. In 2015 Syngenta AG ranked #95 in the Forbes Top of World's Most Innovative Companies. The company's business strategy is complemented by a strong sense of purpose. The long-term success of their business is inextricably linked with the world's efforts to feed its fast-growing population: both depend on sustainable transformation of farming productivity that can be obtained through The Good Growth Plan launched by the company, which consists of:

- increasing the average productivity of the world's major crops by 20 percent without using more land, water or inputs;
- enhancing biodiversity on 5 million hectares of farmland;
- improving the fertility of 10 million hectares of farmland on the brink of degradation;
- reaching 20 million smallholders and enabling them to increase productivity by 50 percent; training 20 million farm workers on labor safety, especially in developing countries;
- triving for fair labor conditions throughout our entire supply chain network.

Research, development and innovation are at the heart of Syngenta's strategy and The Good Growth Plan. Starting with 2013, Syngenta invested $1.38 billion in R&D combining their innovation in genetic and chemical solutions.

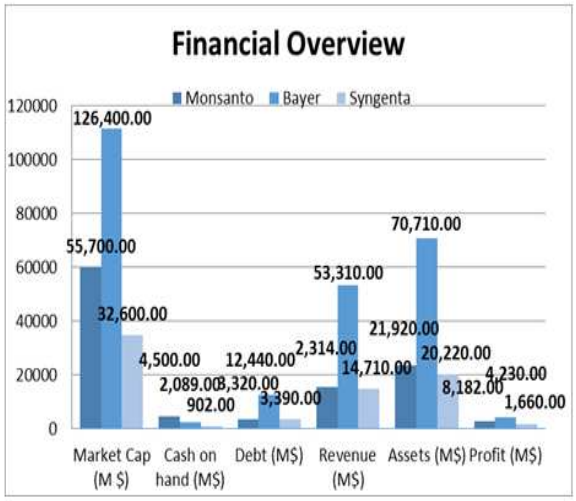

Fig 4: Financial overview 2015 Biotech Multinational companies

Source: own research based on Interactive Data, LionShares, Thomson Reuters Fundamentals and Worldscope via FactSet Research Systems; Bloomberg; Forbes.

The economic performance of these three companies analysed in the case study as of May 2015, can be observed in the above graph. By comparing the values in million US$ of financial indicators such as: market capitalization, cash on hand, debt, revenue, assets and profit between Monsanto, Bayer and Syngenta several conclusions can be drawn. The total value of all outstanding shares of one company is represented by the market capitalization. This financial indicator is calculated by multiplying the shares outstanding by the price per share. Generally speaking, a higher market capitalization indicates a more valuable company.

Comparing the market capital of the three companies, Bayer takes the lead in 2015 with 126,400.00 million US$ followed by Monsanto 55,700.00 million US$ and Syngenta 32,650.00 million US$. This financial indicator represents the highest value of all detailed indicators for Bayer. In terms of profit, Bayer takes the lead again with 4,230.00 M$, followed by Monsanto 2,700.00 M$ and Syngenta 1,660.00 M$. After analyzing the financial indicators and business models of these three major players in the biotech industry, the purpose of this study has been reached and it is pointing out that the industry challenges are leading towards a more intelligent economy.

3. Exploratory Study on a Sample of Availability Concerning Genetically Modified Organisms

Genetically modified (GM) crops offer a variety of potential benefits including higher yields, resistance to diseases and pests, specific characteristics desirable to consumers, and characteristics that reduce production costs. However, decisions about introducing GM varieties must be made in the context of possible unintended consequences including threats to food safety and human health, potential gene flow and other threats to biodiversity, and development of resistance in targeted weeds, pests, and diseases.Acceptance of new food technologies, especially of genetically modified (GM) foods, has recently attracted much attention in research. It has been related to trust and confidence in science, government and biotechnology companies and to socio-demographic factors. Psychological studies of public perception of GM foods have focused on issues as the role of health beliefs, moral and ethical convictions and trust. Although such work provides information on the content of these attitudes, it touches very little on their origins.While scientists define GM by their production method rather than by certain qualities of the end product,GM opponents treat these types of foods as different from conventional foods. Several studies have noted a relation between educational

discipline and GM attitudes with students of the natural sciences having more positive GM attitudes than people from other educational fields.

People's acceptance of GM foods has been shown to depend on their general attitudes towards genetic engineering. Many studies showed that the general attitude towards the application of GM in food production is negative.Therefore, GM products are in general less well accepted than their conventional counterparts.But general attitudes are not the sole predictors of people's attitude towards GM. Some studies provide evidence that although people have a general negative attitude towards GM, evaluations are product specific and not unconditionally associated with the technology overall. For example, some consumers find GM more acceptable when it involves plants, compared to when it involves animals. Others find genetic modification more acceptable when it is used to reduce the use of pesticides than when it isused to reduce prices. A questionnaire based research was developed during 1.03.2015 – 1.04.2015 among 50 persons of Romanian nationality aged above 18 years old which were familiarized with the genetically modified organism notion. The central objective of the research has succeeded to identify the perception that consumers have about the ″new technologies" applied to food, especially the contradictions and challenges that genetically modified organisms can bring. The secondary objectives of the research consisted in the consumer's attitude concerning genetically modified organisms, their knowledge concerning these products based on GMO's, the level of satisfaction obtained by consuming a GM organism based product, the consumption of certain food identified with genetically modified soy content put on sale in the supermarkets from Bucharest, the safety problems concerning GM food, the advantages and also the characteristics of GMO products which mostly influence consumers. The exploratory study has shown the following results as also presented in the figure below:

- increased interest of the consumers for the products made through modern biotechnology
- bioremediation, medicine and genetic testing are encouraged.
- interestingly, some applications of biotechnology are more easily accepted than others, depending on the benefits perceived by consumers according to the available information.

- customers were not very satisfied from consumption of products containing genetically modified soy, which leads to the following conclusion: the assortment of such products should be improved in the future.

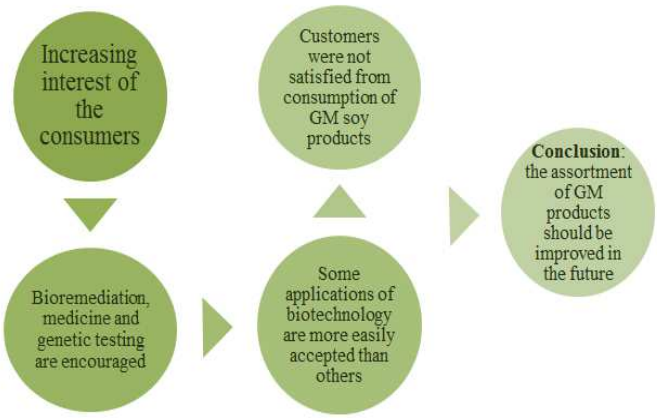

Fig 5: Questionnaire results concerning the consumer's perspective upon GM food
Source: Own research

The distrust of most consumers that do not accept the application of modern biotechnology to food production has led to the proposal of new directives and laws to ensure better food labeling and traceability of genetically modified products or of products that contain genetically modified ingredients. If proper labeling is made, consumers are better informed and can choose between foods that are genetically modified and non- GM.

Conclusions

Several important conclusions have resulted from the present research. This paper aimed and managed to identify the following aspects: the biotech business adds value to an economy affected by the crisis, the business models of the multinational companies involved in the biotech industry, the sustainability of their business, profits and costs and the consumer's perspective upon GM products.

- ✓ Strong companies and their business models have persevered over time, managing to overcome the challenges of the biotech and GMO industry, leading towards a more intelligent economy.
- ✓ Given nowadays economic scenario the governments have to decide if biotechnology support levels are maintained, increased or withdrawn, and if supportive mechanisms are redesigned to change focus on local investment by strong foreign firms vs. domestic entrepreneurial growth.
- ✓ Standard & Poor's Financial Services LLC (S&P), an American financial services company that publishes financial research and analysis on stocks and bonds. Therefore in the S&P 500 subsectors analyzed in the four quarters of 2013, the top 3 performing sectors were Discretionary, Healthcare (which includes the biotech industry) and Industrial.
- ✓ The successful business models of the biotech companies analyzed in the case studies are based on innovation, research and development, combining solutions in a sustainable way, enhancing human health, extending partnerships; having the belief that a significant and sustainable increase in agricultural production worldwide is urgently needed.
- ✓ By comparing the values in million US$ of financial indicators such as: market capitalization, cash on hand, debt, revenue, assets and profit between Monsanto, Bayer and Syngenta – three major players in the biotech industry, it is shown that the biotech industry managed to survive the economic crisis and keep this business sustainable in spite all contradictions.
- ✓ Acceptance of new food technologies, especially of genetically modified (GM) foods, has recently attracted much attention in research. It has been related to trust and confidence in science, government and biotechnology companies and to socio-demographic factors. Studies of public perception of GM foods have focused on issues as the role of health beliefs, moral and ethical convictions and trust.
- ✓ The central objective of the questionnaire based research has succeeded to identify the perception that consumers have about the ″new technologies" applied to food, especially the contradictions and challenges that genetically modified organisms can bring.

In conclusion, GMO based products contribute to high progress in business towards an intelligent economy. The biotech industry managed to keep this business sustainable in spite all contradictions.

The Issue of Representation of Knowledge in Expert Systems for the Granting of Bank Loans in Romania

Claudia Carstea, Faculty of Mathematics and Computer Science, Department of Mathematics and Computer Science, Transilvania University of Brasov, Romania,
carstea.claudia@unitbv.ro
Olivia Florea, Faculty of Mathematics and Computer Science, Department of Mathematics and Computer Science, Transilvania University of Brasov, Romania,
oaflorea@gmail.com

Abstract

The main feature of the procedural methods for knowledge representation is given by the type of operations covered by a procedure. Procedures are triggered by the need to know a specific aspect to which they relate. They can call or can be called from other procedures. Procedural representation of knowledge is achieved in terms of some symbols identifying the procedures or even computer programs, being the way they are used to solving problems. In this paper we want to show the effectiveness of procedural methods in designing expert systems for granting bank loans in Romania.

Keywords: VP-Expert, procedural representation, meta-knowledge, knowledge-base, artificial intelligence

Introduction

Consider any field of knowledge D, an area that is subject to abstraction in an expert system. In these circumstances, the issue of representation of knowledge about the D functions was to identify a relationship R to make the connection in the D with abstracted objects and their representations in model M who synthesizes, in a language of knowledge representation the structure of domain D. [4,9] In essence, knowledge representation about a field consists of building a language model abstract representation and defining a system of relationships between D and R, that would ensure equivalence.

Classification System

The classification system is designed give a finite set of classifications of pieces of knowledge. Classification is the process of systematization of knowledge applied over the crowd parts to determine the groups called classes based on similarities, called classification criteria. Classification process includes two steps:

[1] conceptual classification - the properties of the objects are analyzed in terms of relevance in relation to the objectives utility system to be grouped then the classification criteria;
[2] object classification - the pieces of knowledge acquired from outside are actually placed in classes according to the classification of criterias

Classification must be:

[3] comprehensive, fully cover the set of pieces of knowledge;
[4] goal-oriented to the application's utility system.

A criterion which can not decide if it satisfies the condition of uniqueness of the classification is a criterion for the group. [12] The organization allows a orientations and groupings of pieces of knowledge not by criteria semantic classification system, but by functional criteria resulting from the analysis of different ways of taking the knowledge base of some pieces of knowledge needed to perform processes in resolvent system. [3, 17]

In determining the organizational system for the knowledge base of an application we have to take into account criteria such as:

- access to pieces of knowledge and access to components;
- methods of making inferential processes;

- existing relationships orders;
- knowledge protection against unauthorized maneuvers;
- ensuring the consistency of knowledge base.

Methods of Knowledge Representation

The main methods of representing knowledge in methods of representing knowledge about artificial intelligence systems are:

- representation by predicate of knowledge;
- representation by semantic networks;
- representation in production systems;
- representation by frames;
- representation of the scenarios;
- representation by hyper-networks.

Here there are some exmples designed in VP Expert for systems for granting bank loans to customers (Fig.1) and the calculation of the discount rate (Fig.2).

```

  If gar=depozite then
    punct=4;
```

Fig.1 VP Expert - System for granting bank loans

Meta-knowledge system is a system of representation of knowledge about knowledge and about representations about them. There the following fundamental types of parts metacognition: [10,15, 19]

- Meta-knowledge representation of objects, describing the schemes used pieces of knowledge, representation type is object;
- Meta-knowledge representation of functions, describing the functional templates for parts of procedural knowledge;
- Meta-knowledge representation of relationships, describing the representation schemes pieces of knowledge regarding relationships between any piece of knowledge;
- Meta-knowledge representation of rules of inference and of representation models for describing the rules;
- Meta-knowledge representation of reasoning strategies.

Procedural Representation

Procedural representation it's used for the complex algorithmic processes of knowledge and orientation towards a particular type of problem. [14] For example, analysis of the dynamics of complex economic systems. An important stage is the analysis of structures and extraction of these feedback loops, loops summarizing the implementation and use of policy and decision strategies.[18]

As the structure is represented by elements (objects called nodes) and relationships (objects that represent the connections between them), for problem solving are necessary the qualification nodes, eliminating the knots that do not belong to a feedback loop and feedback loops to determine their consistency check.

The execution procedure refreshes the context and the lists who contain the number and types of nodes. Further, in order to apply the procedure "Drive-LIST-LOOP ', the deletion of paragraphs initial and final independent are necessary, because an attempt to start or pass the algorithm verification can lead to blocking procedure. For this purpose we can use the procedure "remove NOD-INT", which is presented in the Fig.3.

```
for (i=0;i<NVINIT;i++) {
for (k=0;k<RL[V.VINIT[i]-i];k++) {
R[V.VINIT[i]-1]=0;
fin=1;
while (fin!=0) {
        fin=0;
                for(i=0;i<T.NR_F;i++) {
                        if )RL[i]==0) {
                                for (j=0;j<T.NR_F;j++) {
                                        if (RL[j]!=0) {
                                                for (k=0;k<RL[j];k++) {
                                                        if (R[j][k]==i+1) {
                                                                for (I=k;I<RL[j]-1;I++) {
                                                                        R[j][I]=r[j][I+1];
                                                                        RTL[j][I]=RTL[j][I+1];
                                                                        RL[j]=RL[j]-1;
                                                                fin=1;
                }
                else {
                        for (k=0,ii=0;(k<T.NR_F)&&(ii=0);k++)
                                for ((kk=0;kk<RL[k];kk++)
                                        if (R[k][kk]==i+1) ii=1;
                                if (ii==0) {
                                        for (k=0;k<RL[i];k++) {
                                                R[i][k]=0;
                                                RTL[i][k]=0;
                                        RL[i]=0;
                                                fin=1;
```

Fig.3 „Drive-List-Loop" Procedure

Procedural representation can be used in combination with other methods of representation. A frequent use of a procedural representation facilitate the description of actions.

Conclusions

The main advantage lies in procedural methods and in applying heuristic rules. Sometimes, chosen area of responsibility is particularly important and the system response it is in real time, so it is much better than other methods of knowledge representation. A significant disadvantage of this method is quite pronounced because of rigidity of knowledge pieces in making inferences, other than the default procedures.

This is due to the close dependence of knowledge and procedure type of problem to be solved. As the complexity of the issues represented increases its dependence on context and procedural methods it is increasing and the number and complexity of knowledge increases considerably.

For more flexibility in knowledge representation, based on the experience of the analyst and the complexity of the field on which are implemented procedural methods of knowledge representation can be constructed procedures organized hierarchical levels of complexity, which rests on a broad basis and as far as possible, non-redundant basic procedures, which underpin the superior construction.

The increasing of complexity fields of competence of expert systems is due, on the one hand due to increased systems complexity and on the other hand due to the depth of knowledge in the field. It is necessary to solve problems at the intersection of several disciplines and the knowledge needed to be stored and managed in databases is increasing.

Development trends of artificial intelligence based systems for solving complex problems (or cross) reveals a shift of effort from one to several agents competitiveness; to solving the same problem. These trends relying on the design and implementation of a management system to facilitate their efficient operation.

THE DIAGNOSIS OF THE MAINTENANCE MANAGEMENT IN INDUSTRIAL COMPANIES

Ing. Tomáš Kamaryt, University of West Bohemia, The Faculty of Mechanical Engineering, Department of Industrial Engineering and Management, Pilsen, Czech Republic, tkamaryt@kpv.zcu.cz

Doc. Ing. Jana Kleinová, Csc. University of West Bohemia, The Faculty of Mechanical Engineering, Department of Industrial Engineering and Management, Pilsen, Czech Republic, kleinova@kpv.zcu.cz

Abstract

There was developed various maintenance a systems, such as reactive preventive, proactive or aggressive systems and many more. However it turns that many companies do not know what their weaknesses are. and subsequently what are the areas they should have to focus. Out of the systems theory to improve each complex system it is necessary to improve its single components. The presented paper bases on the literature review and field research in the industrial companies. It determines crucial areas of each maintenance system and introduces the complex way to identify its state. Furthermore it advises the process of improvement.

Keywords: maintenance system, management, rationalization, analysis, diagnosys

Introduction

There are various maintenance management systems in the industrial companies. Based on the literature review were identified requirements on the maintenance system. The requirements are the main topics of the previous article (Kamaryt, Kleinová, 2014). The article served also as a base for further research which was aimed to settle down the crucial areas of the effective maintenance system. There were described various maintenance concepts, such as

Literature review

In addition to the requirements there have been developed several maintenance approaches and concepts which aim to decrease the vulnerability to brake-down and lower the risk of failure. There were described many maintenance concepts. Bateman described three basic types of maintenance programs, including reactive, preventive and predictive maintenance, see (Bateman, 1995).

- Reactive maintenance which allows to minimize the amount maintenance manpower and money spent to keep equipment running (Vanzile, 1992), but on the other hand may result in serious machine damages. (Bateman, 1995), (Gallimore, Penlesky, 1988).
- The proactive maintenance strategy refers to all activities that prevent equipment failures from occurring (Swanson 2001). The preventive maintenance reduces probability of equipment failures but often results in higher man power and higher lead time do to the need to interrupt production at scheduled intervals to perform the work.(Gits, 1992)
- Maintenance strategies include Total Productive Maintenance (TPM) which seek to improve overall equipment effectiveness by reducing or eliminating the six major losses (equipment

failures, set-up and adjustment times, idling and minor stoppages, reduced speed, defects in process and reduced yield) (Macaulay, 1988) (Nakajima, 1988), (Weil, 1998)

- Another existing maintenance concepts are described e.g. in literatures like Reliability Centred Maintenance (Moubray, 1997), (Weil, 1998), Business Centred Maintenance (Kelly, 1997), Integrated Logistic Support and Logistic Support Analysis (Blanchard, 1997). These maintenance strategies often require increased commitments to training, resources and integration, they also promise to improve performance. (Swanson 2001)

These models are often very time-consuming to implement or only valid for a special class of equipment. Nevertheless even those ineffective systems in industrial practice often offer interesting and useful ideas. (Kamaryt, Kleinová, 2014). All these models include various areas of the enterprise and lays down different importance on different areas. (Waeyenbergh, Pintelon, 2007). Together with the result of the literature study, it became clear, that there is no universal guideline which areas of the enterprise must be include in the functional maintenance system and which are the crucial ones. The presented article follows previous contribution and determines key areas of every effective maintenance system.

The overall approach

The research combines various methods. In the foreground is the MCA analysis. The MCA analysis is the most used method to compare the transcendent criteria. To perform the analysis successfully it is necessary to use additional method allowing the identification, assessment and sort given data. It was used Likert scale, Saaty method and paper and pen reviews.

MCA analysis

The main part of the research is the MCA analysis. MCA is the analysis which allow to compare heterogeneous criteria and assess the by defined scale. The main principles of the MCA method are defined and concluded in the literatures (Nijkamp, P., van Delft, A., 1977). Within presented study it has been used the analogy to the MCA method and it has been defined following solution procedure, see figure 1.

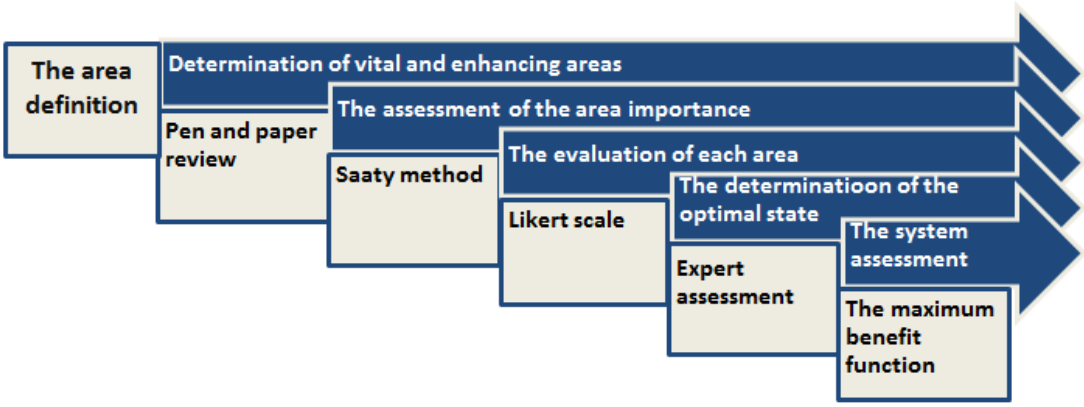

Fig 1: Solution procedure

Research Methods

The figure 2 clearly shows the vital areas of each functional and effective maintenance system. Firstly was defined the key areas. The key areas base on available literature and meetings with managers of the maintenance, logistics, production and other crucial departments of leading industrial

companies. After that according to the available expert literature was the areas split using paper and pen review in to two categories, see fig. 2.

- The vital areas – are the areas which are the necessary condition (Machine evidence and classification, spare parts management and human resources). The vital areas are coloured blue.

- The enhancing areas – are the areas which affect the efficiency of the whole system (maintenance methods, maintenance planning, metric of effectiveness, company standards and connectivity of all areas). The enhancing areas are marked yellow. Furthermore the areas which are crucial for achieving world class maintenance level are marked red.

Paper and pen method

The assessment of areas was performed mainly by the pen and paper review. The structured interview is the technique which allows collect and sort data. The experts were asked to the questions from each area. Based on the answers were defined overall score in each area. The pen and paper review has been was selected mainly because of higher response rate, impossibility to omit the question, qualified moderator and last but not least the certainty of the results. The method description is in the publication (Neumann, W., L., (2007),)

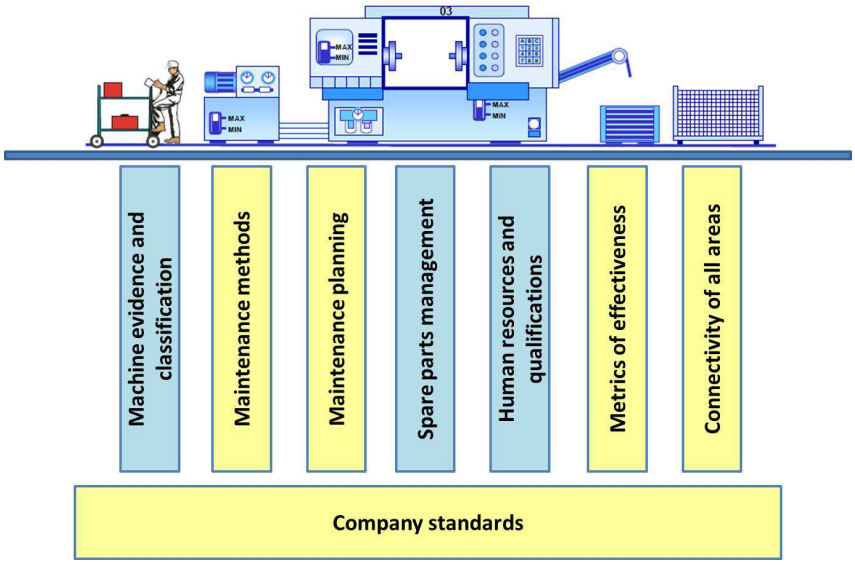

Fig 2: Main areas

The certain degree of implementation within each area is crucial for effective system. But it has been identified that the influence of areas on the final result is different. To identify the amount of influence it has been used Saaty method.

Saaty method

Saaty method (Saaty, 1988) is a structured technique for analysing complex decisions, based on mathematics and social research. Defined areas has been compared with following result, see table 1.

Table 1: The comparison of the areas

Area	Normalized weight
Machine evidence and classification	5%
Maintenance methods	21%
Maintenance planning	9%
Spare parts management	2%
Human resources and qualifications	3%
Metrics of effectiveness	4%
Company standards	35%
Connectivity of all areas	21%

Based on the Saaty method it has been defined three most important areas (company standards, connectivity of all areas and maintenance methods) affecting the level of system effectiveness, see figure 1. The result just underlines the principles of the lean management. Where the main requirement of each system is to have solid foundation where can be the system built – company standards (35%).

Likert scale

The Likert scale is the method which allows measuring the importance of words and the opinion to the given situation. The core of the method is the evaluation of given question by the scale. The scale has one crucial rule – it must have odd number of equally graduated degrees. The main principles and theory basis for the Likert scale is stated in the publication (Neumann, W., L., 2007).

Results and criteria function

The main goal of the diagnosis of the maintenance system is precise identification the efficiency of the whole maintenance. The evaluation is done through criteria function, see the formula 1 below.

$$F = \sum_{i=1}^{n} b_i * v_i$$

The criteria function is maximization. The theoretical minimum is zero point. The theoretical maximum is 80 points.

$$F_{max} = 80\ points = 100\%$$
$$F_{min} = 0\ point = 0\%$$

Bases on the statistical evaluation, paper and pen review was designed the areas on the criteria function. It has been found that the areas are very closely following the border of the normal distribution with standard deviation 25. As well as other natural processes also the companies and its maintenance management systems are subjected to the normal distribution. According to the mathematical theory 68,3% (2 standard deviations) of all companies have some kind of average maintenance system. Other 32,7% are companies below and above the average ones. On the one side the companies which do not deal with maintenance at all and on the other side the companies which

have very good maintenance system. The border has been settled down by the normal distribution – with a single deviation on both sides from median.

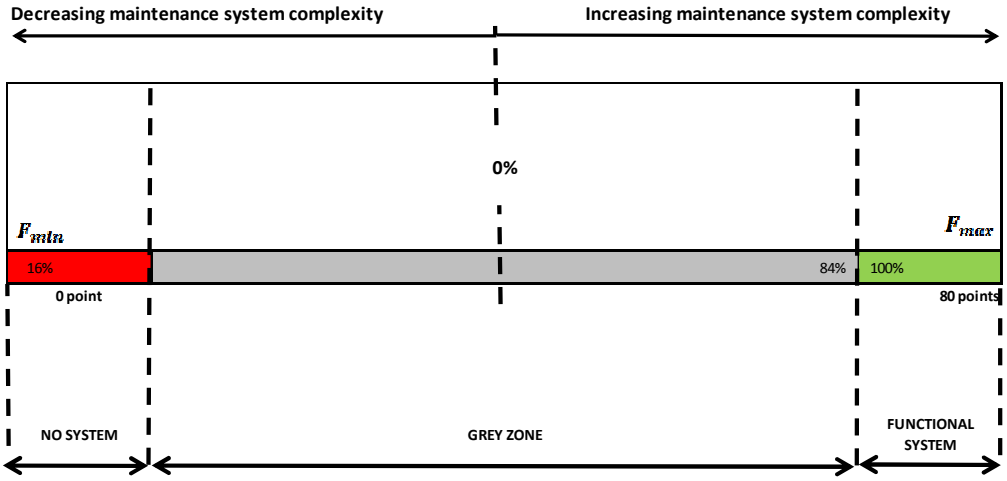

Fig 3: Results – graphical interpretation

The area between 0 and 16% (No system area) indicates that the maintenance is on a very low level. It is necessary to radically improve whole system, resp. to establish completely new maintenance system. The area between 16% and 64% (The grey zone area) indicates that the company maintenance system is on a acceptable level but its efficiency needs to be improved. There are several failures which need to be eliminated. The primary focus should be on the low-scored areas. Finally the green area between 84 and 100% (Functional system area) tells the company managers that the company maintenance system is in a very good condition. There is no need to drastically change any area. However it is vital to follow standards.

The orange bar in the figure 3 and figure 4 shows an example of the automotive company having certain system. It is a typical example of the company struggling with the lack of qualified workers, standards and its pretty developed areas unfortunately can not be directly linked because of different data structure or sort.

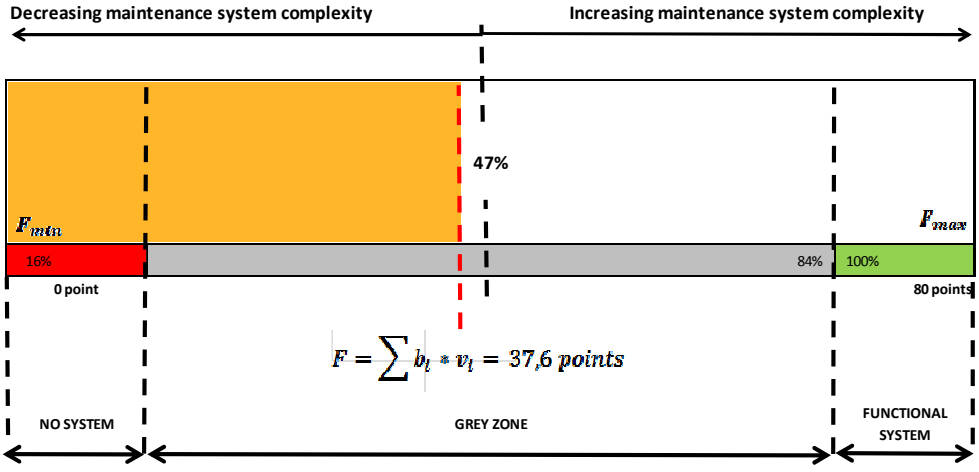

Fig 4: The example of final score

The primary focus should be aimed in to the two most vital areas – on the company standards and the connectivity of all areas together Because these two areas have significant impact on the overall score (see saaty evaluation). Then the focus should be on the area of the human resources. For the detailed analysis within each area see figure 4.

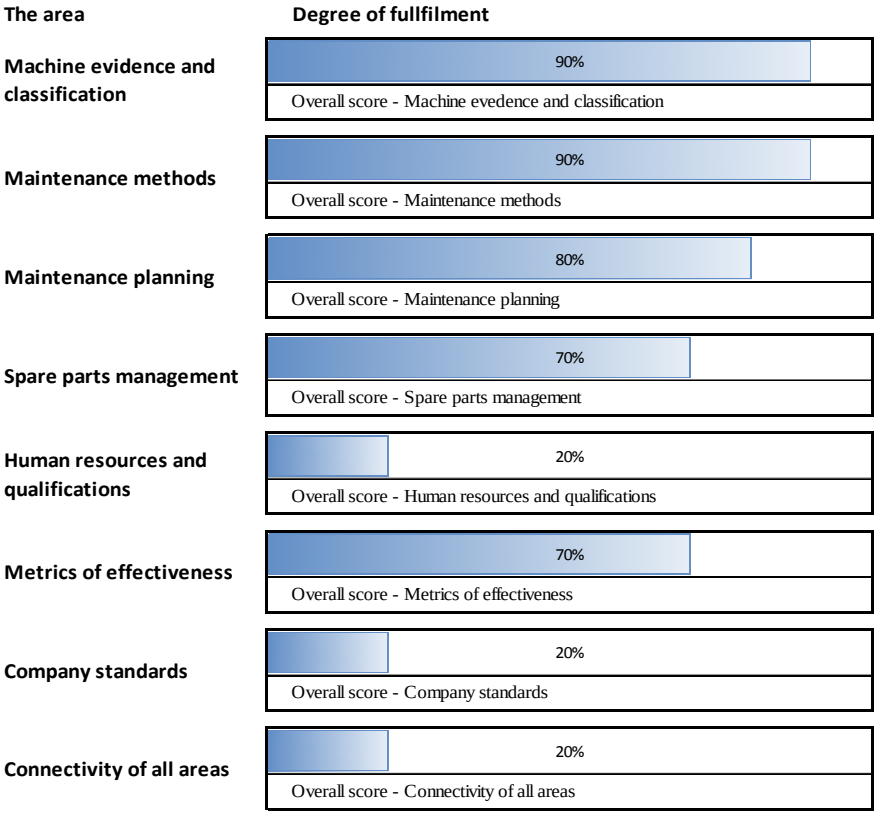

Fig 5: The final score of each area

Conclusion

Many companies want to know their weaknesses therefore are also seeking to the complex simple understandable method how to assess their maintenance management system. The article introduces precisely it furthermore it subsequently advises the company managers what should they do and what are the corrective actions. Between main benefits surely belongs complexity simplicity and low expensiveness. Unfortunately in case of inexperienced moderator can be de results slightly distorted - because of the use of social research method such as Saaty method, Likert scale.

Further research will be focused on the usage of more robust evaluation methods and definition of precise procedure of maintenance process improvement.

Abstract

The cloud is a virtualized concentration of computing resources. A technology with tremendous momentum in terms of evolution and dissemination that's changing the way we process and store data. This technology allows many types of services and is increasingly becoming the infrastructure that enables and supports the next innovations and technologies. Despite its vast and growing adoption, the cloud does provide some challenges, mainly regarding data privacy and security. By reviewing literature, we hope to produce valid interpretations and relations between key concepts in order to better understand the end consumer. Specifically, the main objective is to identify and quantify the key perceptions, knowledge and/or beliefs that will influence the consumer's level of concern regarding the misuse/protection of their data. In order to achieve this, we'll propose a conceptual model, supported by a set of hypothesis and in accordance with the literature review. Despite being a work in progress, this paper can already point out some interesting conclusions on how the user apparently perceives variables regarding trust, privacy and security, benefits and limitations as well as its knowledge/usage of this technology. In the future, in order to proceed with this work, we'll use a quantitative methodology, supported by a cross-sectional inquiry with recourse to structures questionnaires. Because studies of this kind are scarce, we hope and expect to produce new and interesting knowledge for both academic and management fields. To further help with that, we'll present some suggestions to future studies at the end of this paper.

Keywords: Cloud computing; Privacy and security; Concern; Conceptual model

1.0 Introduction

The idea of cloud computing was born in the 60's with Joseph Carl Robnett Licklider's conceptualization of Intergalactic Computer Network, which first appeared in a memorandum sent to his colleagues (Licklider, 1963). A little later, in 1969, Licklider is responsible for enabling the development of the ARPANET project, which basically gave shape to his vision in which all the people in the world would be interconnected and able to access programs and information in any place at any time.

From the year 2000 onwards there's a big push of cloud technology because companies realized that their largest purchases in IT "were often left idle and only fully utilized during peak demand" (Halpbert, 2011, p. 2), leading them to wonder on a better solution in which to better harness that latent processing power. As such, it was only a matter of time and technological evolution until the top tech companies picked up and propelled this technology to the point where now the cloud is a metaphor for the internet and is the abstraction of a complex infrastructure. This technology differs and overlaps the traditional paradigm of computing, due to its scalability, abstraction, economies of scale and dynamically configurable services (Foster, Zhao Raicu, Lu, 2008).

To get a sense of the evolution and size of this technology from a business and economic standpoint, in 2008, Gartner predicted that cloud computing could become as influential as "electronic commerce" (Gartner, 2008), and later it predicted that by 2015 the expenses with IT would ascend to $3,8 trillion mainly because of the cloud.

Also, according to a study conducted by Evans Data Corporation, quoted and discussed in an article from Forbes, by Columbus (2015), the cloud already dominates IT and will increasingly continue to do so as new technological developments arrive, such as the Internet of Things (IoT), which is seen as the next big "explosion" in the technological area. Interestingly enough, this type of connectivity generates huge amounts of data and cloud computing provides the back-end solution for processing and computation of these huge data streams" (Chao, 2011, p. 1).

However, despite its benefits, cloud computing technology struggles with security and privacy issues and, in fact, in an interview given to and presented in the work of Martinez (2013), the Director of EuroCloud, Andreas Weiss, points out the enormous importance of data security and privacy.

According to the Vice-President of the European Commission and responsible for the European Digital Agenda, Neelie Kroes (2014), "the next phase of the internet will be data-centric and driven and directed by connectivity. Cloud computing, big data, the internet of things ... to make the leap of faith into this new world, reliability and trust are prerequisites. But when the Chancellor's phone is sacred, that trust can never be taken as a given by billions around the world, this trust is now lost".

Since the cloud is increasingly becoming the base infrastructure of IT, it’s extremely important to understand it better as well and how consumers react to it.

It’s important to mention the lack of similar studies. Also, the studies are usually purely technical in nature, tend to focus on the business side of the technology and also tend to perform a simple descriptive analysis.

Given these shortcomings, it becomes relevant to proceed with a different application in a different context. With that in mind, we hope to conduct a non-technical study on the end consumer, going instead after the perceptions and values that might influence its concerns towards data privacy and security. Specifically, the final objective is to identify and measure what factors influences the users' concern with the misuse of its data in the cloud environment. In order to do so we’ll start by constructing and proposing a conceptual model, supported by a set of hypothesis, which is what we’ll present in this paper. In the future, in another paper, we’ll try to confirm our model and hypothesis with an empirical study. This study will be based on a quantitative, data analysis, methodology, supported by a cross-sectional inquiry

With this, the importance and relevance of the study becomes apparent, and we hope that this research will add some knowledge on an academic level, for users and administrators.

Regarding this paper’s structure, starting with the review of literature, we will first define cloud computing, followed by the identification of this technology’s main benefits and risks. Afterwards, as we dive into the concerns with data protection, we’ll present the hypothesis as well as the literature in which they were based. Finally, we’ll end with the proposed model.

In the last part of the paper, we present our conclusions for this study, it’s implications and also suggestions for future work.

2.0 Literature review

2.1 Cloud computing

Cloud computing is defined as “a model for enabling convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, services) that can be rapidly provisioned and released with minimal management effort or service provider interaction” (Mell & Grance, 2011, p. 2).

In simpler terms, an explanation of the cloud can be given as a set of computer resources that are always available for use and that are made available and quickly accessible via the internet by a service provider. The service provider creates a pool of resources and then it automatically and quickly configures and reconfigures them in order to supply them to consumer use in a measured way and in accordance to user demand. This measured supply of only the necessary amount of resources insures that there are always resources available for other users (Kok, 2010).

Regarding the benefits and challenges of the cloud, with a literature review of the work of Armbrust et al., (2010), Halpert (2011), Kundra (2011), Mather, Kumaraswamy and Latif (2009), Barnatt (2010), Macias and Thomas (2011), Badger, Grance, Patt-Corner and Voas (2012) and Takai (2012), we were able to identify the main ones which can be observed below.

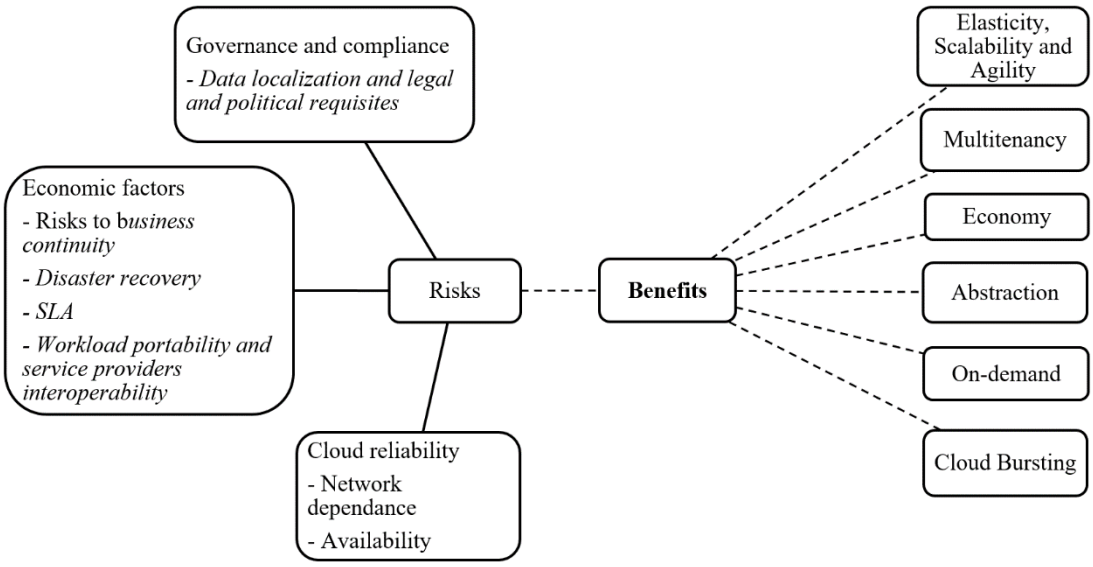

Fig 1. : Cloud benefits and risks

2.2 Concerns with data protection

We now need to review the literature regarding the factors that correlate with concerns with data security, which basically refers to security and privacy, and, though privacy stems and can't exists without security, they're different things, so we'll present them separately.

Normally, security "refers to the degree of protection against loss, damage, danger, and criminal activity" (Changchit, 2014, p. 314). At the same time, "security is both a feeling and a reality, and they are not the same thing", in the sense that there is the actual reality of whether or not a user's data is secured and the psychological side of whether or not the persons feels that his data his secure, which are both independent (Schneier, 2008).

For example, in the case of E-commerce, Yesisey, & Ozok Salvendy (2005) defines safety as the level of security that users feel while they shop online.

This should mean that the perception of security is fickle, it changes with the user's psychological state, awareness, knowledge or experiences.

Flavian and Guinalíu (2006) argue this, defending that security perceived by the user is nothing but mere subjective probability, a situation in which users believe that according to their confident expectations, their personal information (data) will not be displayed, stored, or manipulated by an unauthorized party during its transit and storage.

As to what the main security threats/problems are, Cloud Security Alliance (2013), Jansen and Grance (2011), and also Kwofie (2013), Muijnck-Hughes (2011), Shimba (2010) and Kok (2010) summarize the following: a) data breach; b) data loss; c) account and services high jacking; d) unsecure APIs; e) malicious person (supplier-side); f) abuse of cloud services; g) insufficient diligence; h) resource pooling issues; i) DoS;

Following security, the concept of privacy "varies widely among (and sometimes within) countries, cultures and jurisdictions. It is shaped by public expectations and legal interpretations" (Mather et al. 2009, p. 146), which makes a rigid definition difficult.

That said, there is a definition that appears to have become generally accepted which states that privacy refers to "the rights and obligations of individuals and organizations, with respect to the collection, use, retention and disclosure and disposal of personal information" (AICPA, 2005, p. 2), over a life cycle where accountability and transparency is expected on the part of the organization that provides the service.

In addition, the Organization for Economic Cooperation and Development (OECD), defines privacy as the "the status accorded to data which has been agreed upon between the person or organization furnishing the data and the organization receiving it and which describes the degree of protection which will be provided" (OECD, 2005).

After these brief concepts, in order to go forward with the study on the determinants of data protection concerns we need a research question, which is: "regarding cloud computing technologies, is there any relationship between the perceptions of security, privacy, knowledge, trust and frequency of use, which would allow for a prediction or justification of the consumer's concern level towards the protection of his data?"

Throughout the literature review it's been made clear the importance of cloud technology and consumer behavior.

Along with the review of literature that will still be presented and the research question phrased above, we've formulated a number of hypothesis that will support the conceptual model that is proposed, where we combine the problem and the goal, in a prediction of expected results (Reis, 2010).

Since this study isn't a replica, in whole or in part, of a pre-existing study or model, the assumptions and hypothesis shown from here on out will be based on the review of literature. This means that we'll be the ones doing the interpretation and association of concepts in order to propose both the model and hypothesis.

The first hypothesis is built with the Technology Acceptance Model (TAM) in mind, which can be seen in the image bellow.

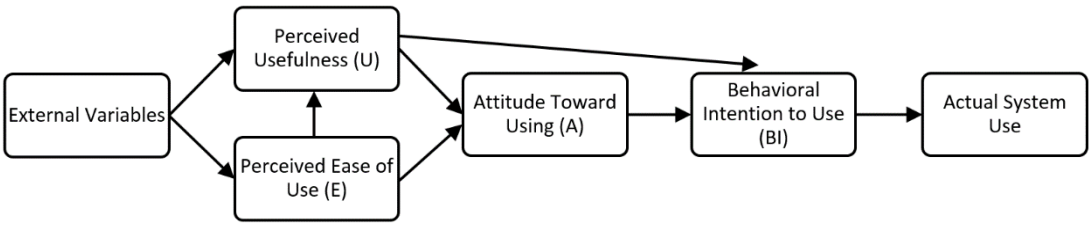

Fig 2.: Technology Acceptance Model

Source: Davis, Bagozzi and Warshaw, 1989, p. 985

Now, one model can't fit into every situation, as there are no absolute measurements nor constructs that can be applied in every situation (Segars & Grover, 1993), which is why there are some other models and even variations or evolutions of TAM. One of the more well-known variants is the Unified Theory of Acceptance and Use of Technology (UTAUT) by Venkatesh, Morris, Davis and Davis (2003). Even though UTAUT has some similarities that can also be mentioned in this work, because TAM is the one that come closest to our overall objectives and framework, with more clearly relatable or "translatable" variables, it's the model we end up choosing above all others, even UTAUT.

That model and its variables along with the work of Lee, Kozar and Larsen (2003), Rogers (1983), Agarwal and Karahanna (2000) and Webster and Martocchio (1992) which study possible external variables to referenced model, will lead us to the 1st hypothesis. Other variables taken in account were "degree of perceived complexity of use of an innovation" (Lee et al. 2003, p. 761), "psychological traits that reflect the willingness/desire to the user using a new technology" (Lee et al. 2003, p. 761), "level of ability/cognitive technologies use spontaneity" (Lee et al. 2003, p. 761), as well as "frequency of use and amount of use" (Hubona & Geitz, 1997).

Since the TAM basically translates the influence of external variables on user's perceptions (and their mutual influence), which in turn influences the user's attitude and behavioral intentions in order to predict actual system use, taking into account the studies of other possible variables, in the mentioned studies, we can argue that "frequency of usage" and "knowledge" might themselves be influencing factors. As such we present below the first hypothesis.

H1: there's a significant and negative relationship between the knowledge/frequency of use of a cloud computing system and the concern with misuse/data protection.

According to the TAM, one of the main variables is "perceived utility", which is influenced by both the second most important variable "perceived usability" and "external variables".

Also, according to the summary elaborated by Lee et al. (2003, p. 761), "comparative advantage" to another solution is a valid variable for the model TAM.

With these 3 variables in mind, we'll argue that the perceived advantages of the cloud will also have a direct influence on concern over data protection, since their influence on attitude and intent towards technology has been study. If the advantages of the cloud are in fact perceived as advantages, useful and facilitators, there may be a significant relationship with the degree of concern towards data protection. As such we present the second hypothesis.

H2: there's a significant and positive relationship between the importance of the benefits of cloud computing services and the concern with misuse/data protection.

On the other hand, it's expected that the more importance is given to any of the cloud's limitations, the greater the concern for data protection will be. Thus, the third hypothesis is as follows bellow.

H3: the concern with cloud computing services limitations is significantly and positively related to the concern with misuse/data protection.

According to the literature, "trust is a psychological state comprising the intention to accept vulnerability based upon positive expectations of the intentions or behavior of another" (Rousseau et al. 1998, p. 395). It's like a relationship that extends in time and depends on the continuous experience of the person with the "object". It's an extension of the concept of security, which also has a psychological component (Rousseau et al. 1998, p. 395) and, according to Shimba (2010) the level of trust in service's security depends on how and how much the vendor can appeal to the feelings of consumers.

Also, trust can be perceived as a two-layer concept, comprising hard trust, which is more rigid and tangible and rational (i.e. validity, coding and security of processes - security oriented) and soft trust which fits in a more intangible dimension (i.e. loyalty to a brand and ease of use – psychologically oriented) (Wang & Lin, 2008).

In fact, some authors even argue that the level of security doesn't affect the user's trust by itself (Pearson, 2012; Nissenbaum, 1999), rather, people who already intend to use a service might have increased trust in the provider if more security assurances are given (Giff, 2000).

Having said that, we intend to confirm that an increase of trust translates into a decrease in concern about data protection, which translates into the hypothesis bellow.

H4: there's a significant and negative relationship between the level of trust in a cloud computing system and service providers with the concern with misuse/data protection.

Next we'll try to observe and measure the opposite of trust, meaning, the perceived risk or threat from several parties involved. Perceived risk stems from trust, or lack thereof and it's a major barrier to technology adoption, especially regarding online technologies. This perception can be defined as a combination of uncertainty and expectation of losses associated with a specific behavior and therefore it's an inhibitor of that behavior (Lourenço and Fortes, 2013).

Also, different entities can produce different perceptions and threat levels and like Lourenço and Fortes (2013) and Mitchell (1999) argue, not only is "perceived risk" able to dictate adoption/use, or not, of technologies but it's also a psychological variable in nature that attempts to measure concern levels.

As such, we present the 5th hypothesis, which is constituted by 4 different sub-hypotheses.

H5: a higher degree of threat to privacy to privacy from specific entities is significantly related with a higher amount of concern with the misuse/ protection of personal data.

H5a: a higher degree of threat to privacy by the Government is significantly related to a higher concern with the misuse/ protection of personal data.

H5b: a higher degree of threat to privacy on the part of private companies is significantly related to a higher concern with the misuse/protection of personal data.

H5c: a higher degree of threat to privacy on the part of advertising is significantly related to a higher concern with the misuse/protection of personal data.

H5d: a higher degree of threat to privacy from hackers is significantly related to a higher concern with the misuse/protection of personal data.

For the five last hypothesis we'll be taking into account the fact that the literature keeps pointing to psychological factors which according to TAM, and even UTAUT, have an influence in what we're trying to measure. With this in mind, we'll be indicating specific situations that we'd argue that should have a psychological footprint and a direct impact on data protection concerns.

Firstly, we'll approach an everyday business practice which is the trading/selling of data. This is something that we believe should influence the user's concerns and we translate that in the hypothesis bellow.

H6: the feeling that results from the sale of personal data by service providers is significantly and positively related with the concern with misuse/data protection.

According to Badger et al. (2012), compliance and governance are a major challenge. The consumer's data is stored all around the world and each country has different sets of regulation and legislation, which means that our data has no global or standard rights regarding its protections, it's all extremely fragment and out of the consumers control. Which means that not only is protection rights an issue, but also, the equality of those rights when compared to data stores in different countries.

With that in mind we want to know whether or not the consumer really does perceive this issue, if that's a problem to them and if it will influence their concern about data protection.

This idea can be seen in the hypothesis bellow.

H7: there's a significant and positive relationship between the importance of personal data protection rights and the concern with misuse/data protection.

Since Ajzen (1991) and Mathieson (1991) define perceived control as set of individual perceptions of how easy or difficult it is to manifest a specific behavior which are capable of influencing the use of a technology, we'll try to observe it's influence with hypothesis presented next.

H8: more control over the cloud computing system implies a lesser concern with misuse/protection of personal data.

Next, we'll be trying a variation of "frequency of use" mentioned in the 1st hypothesis, turning it into "amount of time using" cloud services. This idea is formatted in the hypothesis 9.

H9: the amount of time using cloud computing services is significantly and negatively related with the concern with misuse/protection of personal data.

Lastly, we'll introduce an idea related the current state of technology from a consumer's standpoint in relation to the need to disclose personal data in order to access and use some services. Whether or not disclosing data is an 100% necessity, but, that is the trend, so, how does the user perceive such a thing. Whether or not they agree it's a problem and whether or not it influences the concern with data protection is what we'll be trying to find out with the text hypothesis.

H10: the level of agreement with dissemination of information being a problem is significantly and positively related with the concern with misuse/protection of personal data.

Finally, we present in the following figure the proposed conceptual model, respecting a formal structure of relations laid down between variables.

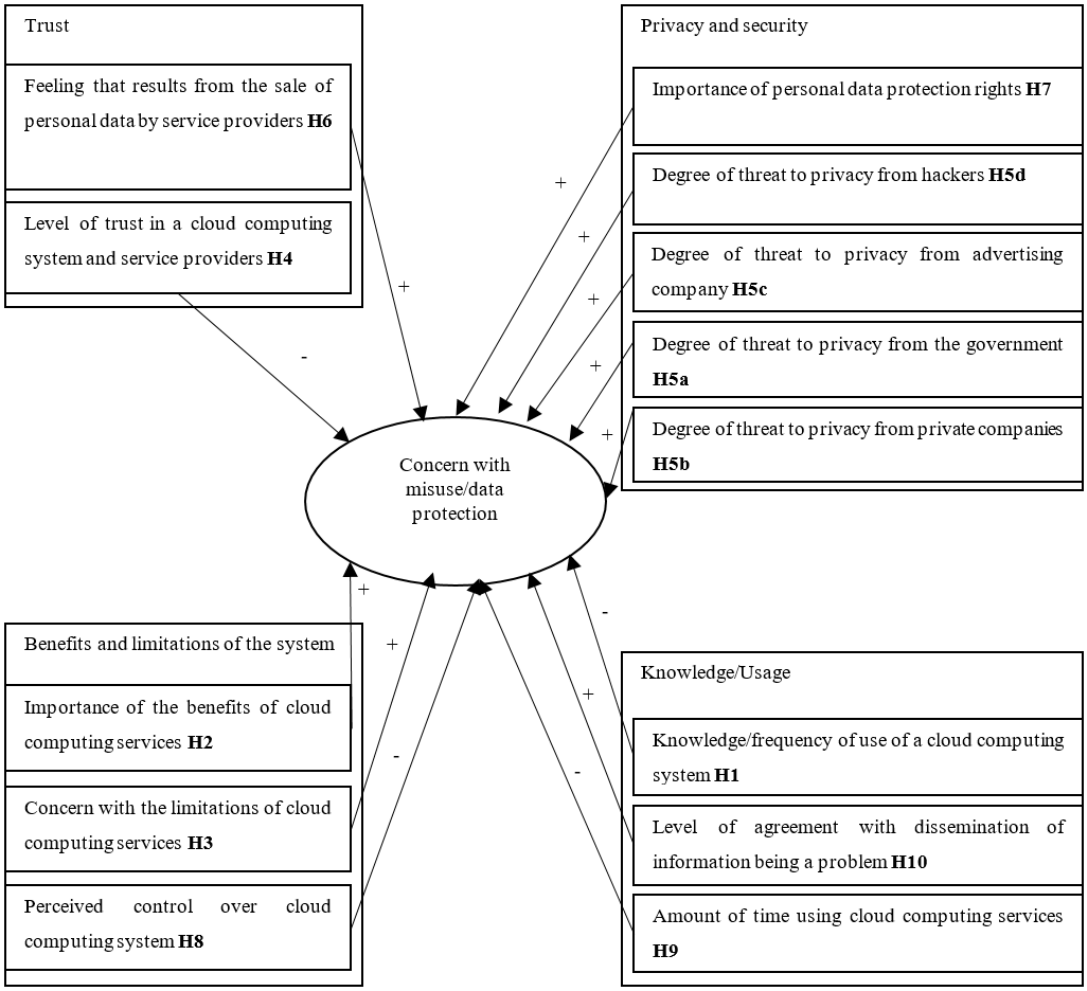

Fig 3.: Determining factors of concern about data protection

3.0 Conclusions

The progressive and accelerated development of cloud technology is creating a need for a better understanding of it, in particular, of the factors that influence its adoption and use. In this case specifically, the concern about data protection.

This technology is increasingly taking on a bigger role in our day-to-day life, our routines, as it gives us innumerable and unimaginable new solutions as time passes.

Still, we must keep in mind the more abstract side of this new era. On the one hand, technology will continue to evolve and expand while on the other, consumers will continue to be the focus and biggest drivers of this evolution.

After the literature review it becomes apparent that cloud adoption is likely determined not so much by the knowledge of the benefits and limitations of the technology, but rather by a set of psychological factors on the consumer's part. What does seem to exert influence are the consumer's perceptions of the technology's usefulness and ease of use as well as trust towards technology it and/or service provider. It's these perceptions and even values, ideologies and user experiences that should influence the consumer's concerns towards data protection and his adoption of the cloud. This means that what's expected to happen is that the consumer will make a two judgment calls while deciding whether or not to use the cloud. First, he'll make a practical judgment call regarding the

technology/service usefulness and ease of use while the second judgment call will pertain to the trust in the service provider and the technology itself. This happens because, as seen, the variables and concepts that should have some influence have a clear psychological nature and are based in more intangible factors.

It is in this context that this study is inserted, in an area with very little research that demands more studies.

With this in mind, this work should become a contribute to the study and modelling of consumer's concerns with data protection. With prudence, we hope that the proposed conceptual model and its operationalization through hypothesis will let us know what determinants influence the consumer's concerns. With them, the conditions to analyze and validate the studied variables should be created, likely by recourse to questionnaire.

As for suggestions for future research, we propose the empirical validation of the proposed model in accordance with the chosen instrument. Also, we suggest creating measurement scales for the model associated variables.

The Role of Universities in the Transfer of Innovations in the Creative Industry in the Czech Republic

Radomila Soukalova, Tomas Bata University in Zlín, Zlín, Czech Republic, soukalova@fmk.utb.cz

Abstract

The growth of the world and European economies is today often conditioned by the creative industry development at the level of individual countries, regions, municipalities. The problem of the creative and cultural industries development becomes a priority area of the National Research, Development and Innovation Policy of the Czech Republic for the upcoming ten years. The objective of the study is to present the outcomes of the analysis of centers for transfer of technologies of selected EU and Czech universities. The analysis focused on the issue of art creative projects in the area of graphics, product and industrial design. The consequent objective is also to suggest solutions for commercialization of creative ideas of art students or art university graduates` in the Czech Republic through the outcomes of the analysis. Contemporary, creativity, creative economies and creative industry become an opportunity for enhancing the competitiveness of individual the EU countries regions. The topic, as well as researches and analyses, stem from the current experience when successfully evaluated creative ideas of art university students, eg. during international competitions, are with great difficulties implemented into practice, and commercialized.

Keywords: creative class, sustainable entrepreneurship, creative centre, regional development, university graduates, culture inovation, transfer creative inovation

Introduction

In the past years, the economic results of numerous countries have showed that the creative economy and creative industry issue becomes a significant factor of economies of many countries. The issue became also the subject of the European Commission discussions and the 2010 document called "The Green Paper - Unlocking the potential of cultural and creative industries" and which supports activities of mapping and consequent development of the cultural and creative industries through structural funds. The Czech Republic joined activities supporting mapping, development as well as rising awareness in these areas (Cikánek et al., 2013). The support of the development of creative industry activities is narrowly linked to the increasing of competitiveness of businesses in the creative industry. Similarly, in other fields with business competitiveness enhancing, it is a question whether to bring "art" or implement innovations, ie. *"to make innovations an everyday business"* (Košturiak, Cháľ 2008, p. 37). Universities become a frequent source of innovations. Universities are inspiring environments, with creative people with inventions and ideas and it could be said that such place is ideal for innovations and their implementation, so-called transfer into the world of practice, also in the creative industries. The objective of the study is to analyze the conditions for the transfer of so-called creative innovations at Czech universities, and to contemplate on the question of "What is the role of Czech universities in the transfer of creative innovations. Scientific terminology is embedded based on the monitoring of scientific published and electronic sources, and partial analyses are then presented relating to creative innovations and transfers of such. A discussion is listed in the conclusion of the means and forms of the transfer cultural creative innovation. The significance of the support and development of the Czech creative industries is amplified also in the approved document called The National Research, Development and Innovation Policy of the Czech Republic in 2016-2020. The document among other things mentions also that the upcoming years, the emphasis will be put on the support of applied research and its link to the private sector. The support will be directed to the key fields such as biotechnology and nanotechnology, digital economics, automotive and air industry and rail transport, as well as traditional fields such as mechanical engineering, electrical engineering, steel industry, foundry and power industry. The attention will be paid also to the cultural and creative industries.

1. Contemporary Situation

What is happening in the markets

Thanks to digitalization and social networking, consumers face a considerable amount of information based on which they make decisions, eg. about a purchase. Customers in the contemporary information turbulent environment become disloyal. Once they obtain a better offer, they do not hesitate to change the purchaser. Information technologies assist customers to become value co-creators, ie. to participate in eg. a development process through a new product testing, or through proposing a color creative design. They find this interesting and it also makes sense. Numerous customers appreciate uniqueness and originality on the market connected with usefulness, and they are open to paying a higher price. Originality often means also an innovation of a product functionality and of its design solution (www.amara.com/alessi). Therefore, the art field is currently frequently linked to the terms of innovation and originality.

What is happening in sectors

The situation in segments with technological development, and in market needs has changed. The term competition has broadened in its content. Numerous factors enter the competition battle and they are uneasy to predict, eg. technological heterogeneity, the power of customers, deregulation of prices and others. Overcapacity is to be found in many segments, and at the same time, the lack of natural resources starts to manifest itself. The recourse to this dissonance may be seen in the search for alternative ways or more economical utilization of natural resources with the use of new technologies which are the accelerator of new ideas and products. The innovation process does not depend solely on raw materials and technologies but is primarily connected to the development of people. The essence of the competition success comprises of the ability to transform information into knowledge and the ability to transform knowledge into a competitive advantage. The necessity to work with the ever-increasing competitiveness of businesses is underlined, as well as the increasing speed of innovation cycles.

The ability to transform information into knowledge is the property only of few talented individuals and their creativity and persistence usually bring extraordinary ideas and "put things in motion". Businesses, who wish to innovate and compete, exhibit great demand of talented individuals (Šviráková, 2013).

The role of universities in the process of innovation

Universities and the research and development centers and workplaces play an immense role in the process of innovation and competitiveness development in the economic as well as the social system. Since their establishment, universities represent the concentration of educational and development activities which in many cases bring creative and innovative solutions. Universities are the soil guaranteeing an independent research and liberal knowledge with its rational and ethical dimension, its morals and consciousness, shared by an independent community of teachers and students. The fundamental principles of universities mission are anchored in the document for European universities (signed on 18 September 1988 at the University of Bologna). One of the key principles is oriented to the fulfillment of educational, research and development activities in accordance with the current status of science and with the needs of the society. These activities should enhance creativity in science, creative and educational activities. A no less significant role of universities lies also in the realization of cooperation with the world of practice in order to establish favorable conditions for graduates, and also, in order to build cooperation on innovations and creative solutions transfer into the practice. (National R&D Policy 2016).

2. Theoretical Basis

Creative and cultural industries

The document, approved by the Czech government, sets new priorities of the national policy in science, research and innovations in 2016 – 2020 also for the cultural and creative industries. In 2002 Florida (Florida, 2002) stated in his articles that the most prominent sources of a country are its people and their individual creativity, talent and skills. And particularly segments based on these sources are considered

as the most significant movers of innovation processes of the particular country. These segments are since the 1980s called the creative industries (Žáková, Kraus, 2014). Benefits of these industries for national economies may be observed in the creative segments bearing innovative ideas. The creative industries inspire other businesses and entities to innovation activities. The application of new technologies accelerates innovation processes of the producers of new technologies. Creative industry entities closely cooperate with other segments by means of creative inputs, eg. ideas for new products, services, marketing support for innovations and new products.

The creative economy according to Howkins, (2001 p. 8), contain scientific, research and artistic activities under the intellectual property rights protection. According to Howkins, the creative economy is based on four areas, on the copyright, patents, trademarks and designs. Among the partial industry segments of the creative economy also the following may be counted: research and development, software, radio and television, design, music, film, toys, advertising and architecture, handicrafts, video games, fashion industry and arts.

The terms of creative and cultural industries are defined in distinctive ways by numerous authors. Eg. The OSN defines the creative industries as industries orientated at outputs stemming from the intellectual property rights. The cultural industries generate outputs within the traditional art, literature and/or cultural heritage.

Space for innovations

It could be said that we are surrounded by successful innovation on every step and numerous of them are not based on any complex technical problem, but on a simple idea, which brought something new that captured one`s attention and got its supporters (Košturiak, Chál, 2008). Innovations can be spoken about in two areas. The first area concerns the subject of innovation, ie. what is to be innovated, eg. how to innovate a product, services, how to create new markets and business systems. The other area is related to innovation abilities of businesses, ie. how to develop innovation skills, what areas of the business are to be innovated in order to ensure a permanent growth of the company. Managers of businesses approach innovations from different perspectives. Some want their companies to "keep alive and operate", others want the business to flourish. The first strategy promotes economizing, eg. saving materials (saving has never brought wealth), incessant improvements (is the condition for the existence, not for the growth) or copying successful projects, this does not lead to the growth.

Under the second strategy of "achieving flourishing development", businesses should concentrate their efforts on logistics, product development, and onto strategic innovations eg. acquisition of a new know-how, acquisition of new products to extend product lines, acquisition of a new market or distributional channel. These areas may be of a great innovation potential and their development relates to inventiveness and creativity of employees. Strategic innovations cannot be carried out without the human potential development and support which is characterized by four areas: intellectual, physical, emotional and moral potential. (Košturiak, Cháľ, 2008). Emotional and moral potentials represent values for building creativity and performance of businesses and thus for establishing conditions for innovations.

Culture and creativity as an innovation source

Application of research and development outcomes, of ideas and creativity of individuals in the practice is the prerequisite for continual innovation activities and for enhancing the competitiveness of the national economies. Qualified employees, professionals and educated and creative people are the strategic sources of innovations, with the concentration of whom so-called creative ecosystems are founded. They are environments with a high accumulated knowledge and favorable conditions for the creativity development (Žáková, Kraus, 2014).

Creativity is defined as a capability to connect existing knowledge, to generate new ideas and transform them into a useful whole. Creativity is concerned a strategic intangible inexhaustible material. (Arfaya Peters, 2010). The pre-requisite for enhancing the competitiveness of localities, regions or countries, is the ability of the society to maximally utilize their creativity potential. According to the UNCTAD study (2010), we distinguish 4 basic types of creativity: Cultural, scientific, economical and technological.

The study primarily discusses the cultural creativity which includes imagination and the ability to generate original ideas and ways for the interpretation of the world. These are mostly expressed by text, music, image. The cultural creativity is often related to the scientific creativity which includes curiosity and will to experiment and form new links of existing knowledge to solutions of a specific problem. The typical area of linking cultural and scientific creativities is eg. design.

Innovation and culture overlap to a certain extent and the creative industries occur directly on their borderline (Hautamaki, 2010, p. 16). The cultural creativity may be characterized as an ability of people (artists) to creatively think and express regardless of the conventional rules. These people thus develop new ideas, ways leading to new products and services. The cultural creativity does not only relate to cultural products but also leads to the development of information and communication technologies as part of book, music or newspaper sales via the Internet. Film technology, the ways of its distribution thus get innovated in terms of the cell phone applications, product design, computer games improvement, etc.

The importance of creative industries for the economy is depicted by the Fig. 1. Here, innovations are represented by educated and creative people through scientific and cultural output. (Žáková, Kraus, 2014 p.5)

3. Analysis Areas

Methodology, objective, research problem

The research problem, dealt with in the study, builds on the experiences showing that successful creative student projects, eg. design proposals, are highly valued at international competitions (Trilobit, Red Dot, 2015´), however, their transfer into the practice is sporadic, almost null. In 2008 up to 2014, 314 industrial property applications had been submitted on behalf of the TBU in Zlín (Czech Republic). Out of the total 150 of the registered designs, especially product designs, almost none was in the form of a license transferred into production and practical use. The analysis stems from the assumption that the transfer of innovations within the cultural and creative industries is not at European and Czech universities realized by means of traditional technology transfer centers. The aim of the study is to verify the presumed fact relating to the transfer of creative innovations, to identify ways, or new subjects leading to the real transfer of creative innovations.

The methodology follows on the primary research which was carried out in the form of available information collection through websites of monitored institutions. Criteria had been established according to which the information was analyzed.

4. The Analysis of Technology Transfer Centers in the EU and in the Czech Republic in Relation to Artistic outputs in Product, Industrial and Graphic Design

The analysis of selected universities in the EU

The analysis was processed with the use of materials from 2010 written during the project called the "Effective Transfer of Research and Development Outputs in Production and their Subsequent Utilization" (EF-TRANS). The analysis of the system of commercialization of research and development outcomes in selected EU countries (Finland, Sweden, Denmark, the Netherlands and Norway) was one of the partial reports of the project. They were the countries with a very high innovation potential. The analysis was carried out by the research team of the Technology Center of the Academy of Sciences of the Czech Republic. The analysis also included particular prestigious universities and their processes leading to innovation transfer. These universities were also the subject of the below-described research. The results of the analysis withing the EF-TRANS project were used as the base for the analysis of commercialization of outcomes in relation to artistic outputs, particularly as a part of innovation solutions in product, industrial and graphic design.

The main criteria of the analysis became those which in their content complied with the research subject of the project of IGA TBU: the existence of the art faculty/institute/studio, the focus of the technology transfer center, whether the content of activities relates to design, project focus (if stated)

Finland

Aalto university school of science and technology. The university has a faculty of arts: The school of Arts, Design and Architecture, http://arts.aalto.fi/en/**.** The Faculty claims to deal with research, to cooperate with the commercial sphere, research teams and areas of research are described. The specific projects are not listed. They offer services for these researches.

University of Oulu, http://www.oulu.fi/english/departments, there is no school of arts, only the faculty of urbanism and architecture

Sweden

Stockholm University http://www.su.se/english/ - no art faculty. There exists a so-called innovation office which ensures cooperation with the commercial sector in the form of consultancy, also serves as an incubator; in addition, the university runs several specialized research centers, there is no mention of new product designs, etc.

Gothenburg University http://www.gu.se/. There are two faculties of arts: Faculty of Fine, Applied and Performing Arts, http://konst.gu.se/english and Faculty od Arts http://www.gu.se/. The faculties focus on the following research areas: Faculty of Arts: Cultural Sciences; Historical Studies; Languages and Literatures; Literature, History of Ideas and Religion; Philosophy, Linguistics and Theory of Science; Swedish**. Faculty of Fine, Applied and Performing Arts**: Design; Crafts; Digital Representation; Photography; Independent Filmmaking; Fine Art; Musical Performance and Interpretation; Performance in Theatre and Music Drama; Literary Composition Poetry and Prose; Music Education; and Arts Education

Denmark

Technical University of Denmark http://www.dtu.dk/english. The university has no art institute. The primary research focus and cooperation with the commercial sector lies purely in technical and natural sciences and technologies, and corresponds to the main specialization of the faculties.

Norway

University of Oslo, http://www.uio.no/english/. The research focus of their centers agrees to the faculty specialization, the Faculty of the Social Sciences has the Center for Technology, Innovation and Culture, nevertheless, there are no projects related to design etc. They are rather scientific projects in the theory of culture.

Oslo National Academy of the Arts http://www.khio.no/en/. There are 6 arts departments (the Academy of Opera, Dance, Theatre, Design, Art and Craft). Research activities, cooperation with the world of practice are not specifically presented here.

University of Bergen, http://www.uib.no/en. No school of arts, the Faculty of Humanities, the Faculty of Mathematics and Natural Sciences, the Faculty of Medicine have their own research centers specializing in solving projects associated with the study fields and scientific research.

Bergen University od Art and Design http://www.khib.no/english/. The only university of arts in Bergen with specialization in arts and design. Research activities focus on the research of arts, they have their own research board. The Department of design university declares a Design incubator on their website (no detailed information). The university disposes of their own space for presentation of interesting research or artistic activities called Room 8. Projects focuses are listed on the website where information on research activities and projects in arts and design are provided.

Analysis of technology transfer centers in relation to the transfer of creative innovations in the Czech Republic

Masaryk University – The Technology Transfer Center. The structure form at university: integrated into the organization structure of MU, one of their workplaces. The contact via http://www.ctt.muni.cz**.** The analysis with the established criteria found that the presented projects were usually solved especially in cooperation with a particular business, which at the same time participated in the development. In their contents, the projects focus on the development of new technologies. An incidental product or device design is solved as mere complimentary parts of projects.

Czech Technical University in Prague – Inovacentrum. The Technology Transfer Office is attached to the CTU structure as one of its other constituent parts, contact via: https://www.cvut.cz/inovacentrum**.** The TTO presents a project called INOVAJET, which is the business incubator of CTU, which provides a comprehensive support to starting innovative businesses including a consultancy over their business plan. They organize educational activities, provide office spaces, support participation in competitions for start-ups, offer accounting and legal guidance, assist in building the network of contacts, corporate culture and identity. The help lasts for 18 months and is divided into the following stages: Warm up, Focus, and Accelerate & Develop.

The University of South Bohemia in České Budějovice – the Academic Center for the Transfer of Technology at the University of South Bohemia. The center has two offices, The Office of the Transfer of Technologies of the USB is a part of the rectorate of the USB, the other part is incorporated under the Biology Center ASCR (http://www.jctt.cz/). The projects are focused particularly on fishing, agriculture (preparation for cereal seed treatment, a recipe for a jam with stevia, development of gluten-free bread mixtures). The Center does not conduct an independent research, it serves as a mediator between the scientific research and the commercial sphere. There is no faculty of arts at the USB, therefore, activities focused on the transfer of technologies are compliant with the specialization of faculties.

Technical University of Liberec – The Institute for Nanomaterials, Advanced Technologies and Innovation (CxI). The Institute is a part of the university structure as one of the all-university workplaces, (http://cxi.tul.cz/). Conducted projects focus on the research of nanotechnologies in nanostructure analysis and their measurement, nanomaterials in natural science, nanotechnologies in IT, machinery construction and industrial technologies. The projects are primarily orientated to nanotechnologies and mechatronics. There is a department of arts and architecture at the TUL, however, the activities associated with the transfer of creative innovations or cooperation with practice are not presented.

Charles University in Prague – The Center for Knowledge and Technology Transfer. The Center for Knowledge and Technology Transfer of Charles University is one of so-called other university units, it is governed by the rector. (https://www.cuni.cz/UK-765.html?poid=1382369926888381) **.** Project focuses are not specifically given. The Center publishes the so-called Catalogue of Innovation Opportunities which is innovated annually. The Catalogue is a portfolio associating products, specific offers of contract research and other forms of investment opportunities from all departments of Charles University in Prague. We annually file new innovative technologies and the portfolio is updated regularly. CPPT considers individual contact with a business to be the most efficient form of cooperation, when we identify the specific fields of interest. CU has no faculty of arts and it does not specify any details of the realized transfers. Palacký University in Olomouc – the Science and Technology Park

The Park is a university institute under UP in Olomouc (http://www.vtpup.cz/). The University has no department or faculty of arts, the focus projects cannot be identified, the Park serves especially as a

platform for counseling, for communication with businesses, and for submitting project applications. What is interesting is the structure of activities of UP Business Club and others, which basically copies activities of coworking centers.

Technical University of Ostrava – the Innovation Support Center. The Center is incorporated into the university structure among so-called other units. The following departments belong to the Center: Commercialization, Business Incubator, Popularization of Science and Technology (http://cpi.vsb.cz/cpi/uvodni-stranka-cpi/)**.** The department of commercialization administers an offer and demand website which publicizes offers of workplaces for cooperation with the commercial sphere, and the demand of the application sphere http://agent.vsb.cz/o-nas/. The projects are in their content coherent to the specialization of individual faculties, ie. in energy utilization, metallurgy or engineering. The Center serves as a service and support element creating a platform for the support of research and development. The University has no faculty of arts. The philosophy of the offer and demand portal brings a great positive feature which may increase mutual informativeness between the academia and application sphere.

Institute of Chemical Technology in Prague – not found, no faculty of ATS.

The University of Economics in Prague – not found, no faculty of ATS, too. The University is a partner in the project called Centers for Technology Transfers – under the TC ASCR. The CeTT organizes tutoring sessions for the particular target groups.

Brno University of Technology – the Center for Technology Transfer. The Center is incorporated into the BUT structure as a university workplace (https://www.vutbr.cz/ctt/). It works as a mediator between the academia and application sphere, between scientists and businesses. The conducted projects lead to a wide scale of technologies (medicinal issues, thermal flow, microscope prototypes, the chemical composition of loam, automotive and traffic engineering). Even though the BUT facilitates also a faculty of arts, no artistic impact can be traced to the technology transfer. According to the presented conducted projects on the website of the Center, it is a long-term cooperation of businesses with development workplaces where impulses come from the application sphere. The proposal of the solution of cooperation offer for the application sphere may be evaluated as positive. The Center operates as a mediator and service support for cooperation.

The University of West Bohemia, Plzeň – New Technologies Research Center. The Center is incorporated into the university structure as a university workplace, contact via http://ntc.zcu.cz/kontakt/ **.** Projects focus on material and laser technologies, stress analyses, flow and heat transfer, modeling and monitoring human body, interdisciplinary activities**.** Although UWB has a department of arts, in the presentation of the activities of the Center, no activity associated eg. with design etc. was proved. Ladislav Sutnar Faculty of Design and Art does not deal with technology transfer on their website (nor with any similar research).

The University of Pardubice – the Center for Technology and Knowledge Transfer. The Center is incorporated into the university structure as a university workplace, (https://vav.upce.cz/domu)**.** The Center established in 2012, has been being developed under the project, and its activities in technology transfer have not been presented yet. The University has the Faculty of Restoration, however, its research is focused on the development of new restoration procedures and technologies. It can be said by the account of offered technologies that a plausible transfer will be specialized in the development of plastic working, traffic engineering, electrotechnics, building industry, water management, etc.)

The analysis of school and faculties of arts in the Czech Republic

The Academy of Arts, Architecture and Design in Prague (the Department of Design, Applied Arts and Graphics). The websites of individual departments inform about students` successes. Frequently, the proposals and designs awarded in various competitions are created in cooperation with businesses who initiate the particular project.

Ladislav Sutnar Faculty of Design and Art of UWB in Plzeň. The websites inform about exhibiting activities and successes of students in competitions. No mention of a cooperation with the commercial sphere has been found, nor about solving projects with innovation potential within the frame of the specialization of the faculty. (http://www.fdu.zcu.cz/cz)

The Faculty of Arts and Architecture of the TUL Liberec. The essential information on cooperation with businesses is missing on the website, as well as on project solutions, etc. (http://www.fua.tul.cz/)

The Faculty of Fine Arts of BUT Brno. The website contains elementary information on realized projects and exhibitions, however, there is no mention of student successes, nor of cooperation with the practice. (http://www.ffa.vutbr.cz/).

4. Outcomes and the Analysis Findings

EU: Centers for technology transfers at universities in the EU countries deal primarily with research and development associated with specializations of individual faculties. If there is an arts faculty at a university, it usually devotes its activities to research, however, these areas are not included in technology transfer. Research is solved in cooperation with the commercial sphere as well as internationally. It may generally be said that centers for technology transfers focus especially on the research of technologies, health care, environment, energetics, agriculture, etc.

Based on the research we may assume that the so-called cultural creativity concentration is organized partially in an independent way on the academic grounds (eg. Inkubator Bergen) or utterly independently on academic activities (commercial coworking centers or different forms of hubs).

Czech Republic: CTTs at Czech universities operate mostly as mediators between academic teams and application sphere teams. They offer a number of services in areas of project application processing, intellectual property solutions (registration of patents, industrial designs, licenses, etc.). They offer educational activities in intellectual property and knowledge management, etc. Numerous centers run also business incubators and thus assist with the realization of new ideas. In the case when cooperation with application sphere ends up by technology transfer, it is often focused on areas which are compliant with the research focus of individual faculties. In the case of the solution of an innovation project, eg. solution of a product design, this is processed presumably as a complementary part of the entire project, not as its fundamental objective. At faculties of arts or independent art universities, the creative innovations transfer is not dealt with systematically. When they work with creative projects with creative innovations, it is always in cooperation with a specific submitter, business. Most frequently it is a collaboration on particular creative projects, companies encounter in their everyday business.

The creative innovations transfer activities do not have any systematic solutions from the side of the analyzed Czech universities. No center has been proved to exist which would support the concentration of the cultural creativity (as was explained above).

Conclusion

Based on the analyses, it can be concluded that establishing of creative centers must be supported for the transfer of creative or cultural innovations. This would create space for concentration and interconnection of creative and scientific innovations. Such a connection is rather difficult to implement within individual faculties and departments (as becomes evident from the analysis) as well as universities. A problematic issue arises: who should establish, finance and operate the creative space. In 2015, more than 40 coworking centers and hubs existed in the Czech Republic, however, almost all of them have concerns about their long-term sustainability and economic prosperity. The risk is high particularly for smaller municipalities where the creative potential is insufficient, and thus, numerous centers become mere premises lessors. The activities supportive of centralization of creative and scientific innovations remains primarily at universities. They should initiate, deepen and expand knowledge. Universities with their knowledge base should become progressive coordinators and engines for creative, cultural, scientific and technological innovations

Road Map of Service Quality to E-Government Service Quality

Taiseera Al Balushi, Department of Information Systems, College of Economics and Political Science, Sultan Qaboos University, Muscat, Sultanate of Oman, taisira@squ.edu.om

Saqib Ali, Department of Information Systems, College of Economics and Political Science, Sultan Qaboos University, Muscat, Sultanate of Oman, saqib@squ.edu.om

Abstract

Governments can offer more services to citizens and businesses by utilizing advancement in ICT. Increasingly citizens find it easy and cost effective to reach government services online. On the other hand, as governments thrive in providing citizens services via electronic channels they also need to consider those quality factors that impact citizen's willingness to use the services. This paper investigates available literature for frameworks and models in the area of e-services, e-service quality, and e-government service quality taking into account the classical SERVQUAL model. The paper provides a roadmap of key quality attributes that are substantial to consider when offering e-government services.

Keywords: e-government, e-government services, quality models, quality attributes, service quality, dimensions.

1. Introduction

The advancement in e-service quality forced government to adopt changes and enhance their facilities by providing e-services in government domains. The preliminary study by (AlBalushi and Ali, 2015b) found that Content, performance, security, personalization and citizen Involvement were the major key trends used from 2000-2014. The services offered by the government require more satisfaction in terms of service quality. In larger aspect the area of service quality comprises of no of definitions, models and measurement instruments. Different authors presented and quantify service quality domains with aim to quantify the e service quality in large and provides the best possible ways to enhance the quality of service.

While in early development of e- government services, the prime focus of authors was on technical flaws and design aspects of services, but the innovation and advancement is services tends the user believe towards the satisfaction of services provided by the e-government websites.

The services provided by the e-government websites plays an enormous role in capacity building of user confidence and trust. The reliability of information and attraction towards the services engages the citizen emotionally and allows him to utilize the e-government services frequently. Therefore, the public institutions are required to place citizen requirements in priority to facilitate the aroma of satisfaction for enhancing citizen interest in availing e-government services.

The objective of this research is identifying the core dimensions of e service quality that helps to quantify the weak areas of e service quality in perspective of citizen involvement in e-government services. This aims to provide quality of service up to that satisfactory level which assured citizen to have reliable, secured and prompt services.

2.0 Literature Review

2.1 Frameworks and Models for Service Quality

Evaluating the service quality and their attributes is becoming the most emerging research area for enhancing e-service quality. The concept of evaluating service quality is presented by (Parasuraman et al., 1985) in SERVQUAL framework. SERVQUAL is well recognized and trustworthy framework for the

evaluation of service quality in traditional retail industry. The framework considers different parameters (word of mouth, personal need, past experience, expected service, perceived service, service delivery, external communication to customers, translation of perception in service quality , management perception of consumer expectation) for the evaluation of service quality(Parasuraman et al., 1985).(Parasuraman et al., 1988a) revised SERVQUAL and quantified the service quality with five Key dimensions (reliability, assurance, tangibles, empathy and responsiveness). Several authors((Long and McMellon, 2004, Cristobal et al., 2007, Rotchanakitumnuai, 2008, Alanezi et al., 2010, Sharma et al., 2013, Papadomichelaki and Mentzas, 2011) founds SERVQUAL as a key framework for the evaluation of service quality in different domains. The requirement and vastness of different service quality domains needs mediation of determinants provided by the SERVQUAL accordingly (Lee and Lin, 2005).

The environment of e services is entirely different from the traditional services. The parameters available for the evaluation of service quality are strictly bound to identify the gaps between the delivered service quality and the service quality received by the user. The scope of the framework is limited only to the traditional services where, user is directly interacting with the service provider. Therefore, the limitations of SERVQUAL don't allow it to use for the evaluation of any other services except those where user is directly interact with service provider. The dimensions of SERVQUAL have both tangible and intangible items.

The tangible dimension of SERVQUAL required equipment, staff, physical presence of staff etc,(Parasuraman et al., 1985, Parasuraman et al., 1988b) for the evaluation of service quality which is quite indifferent from the aspects of e service quality where staff, equipment don't present to have any impact on the measurement of e service quality. Therefore, it can be assumed that, the tangible dimension of SERVQUAL make it more specific for retail industry and cannot be trusted for the evaluation of e service quality.(Lee and Lin, 2005, Yoo and Donthu, 2001, Santos, 2003, Ladhari, 2009, Achchuthan et al., 2014, Hussain, 2014) used intangible dimension instead of tangible dimension in context of e service quality.

Another important dimension of SERVQUAL is empathy which refers to the caring and individual attention for customer along with assurance dimension delivers the confidence which plays an enormous role to increase credibility, sense of security/privacy and trust in customers. Whereas, reliability dimension along with responsiveness dimension encourages the customer to use the services confidently in stipulated time (Parasuraman et al., 1985, Parasuraman et al., 1988b). The above discussion concludes the fact that the available dimensions of SERVQUAL are more citizens centric but the presence of tangible elements in SERVQUAL has limited the scope and allows it to use only in physical retail environment rather than other domains of service quality. Thus, the limitation of SERVQUAL and the advancement in information technology allows building new framework in different domain of service quality.

The next section of the paper contains discussion about the framework and models available for e service quality.

2.2 Frameworks and Models for E-Service Quality

Most of the retailers and services provider facilitates their users with e services. One of the major growing concerns in the service industry is to maintain the better quality services. The quality of service depends upon the service acquired by the user/customer. So, there is need to identify the parameters or dimensions to quantify the e service quality. Different researchers identified and discussed different dimensions to quantify e services quality. The service quality of e commerce website is quantified in SITEQUAL(Yoo and Donthu, 2001). (Barnes and Vidgen, 2002, Loiacono et al., 2002) also measures the website service quality by utilizing the general dimensions in the e commerce domain, the dimensions utilized were mainly focus to evaluate the impact and intent to re-use the website. In context of service quality in e commerce websites,(Loiacono and McCoy, 2004) reformulate the SERVQUAL and identified dimensions(tangible, assurance, reliability, purchasing process, responsiveness) to quantify

the confidence of customers along the human behavior of providing service quality. Although (Parasuraman et al., 2005) identified multiple item scale E-S-QUAL with dimensions to evaluate the routine and no routine operations. The dimensions available for routine operations (fulfillment, efficiency, system availability, and privacy) focus on the traditional attributes of maintaining service quality whereas, the dimensions for non-routine operations (responsiveness, compensation and contact) focuses only those services that should be provided after sale. While, (Cristobal et al., 2007)identified four dimensions (web design, customer service, assurance, order management) to measure the perceived quality of a website (PeSQ) in context of e retail environment. The dimension web design of PeSQ refers to the availability of information whereas, customer service and assurance refers to the service quality and loyalty, while the dimension order management is the physical dimension which deals with the availability/booking/delivery of the equipment. Thus, the argument supports that PeSQ model is valid for the measurement of perceived service quality of websites.

The eSQ model is presented by (Ladhari, 2010) with different dimensions (website design, reliability/fulfillment, responsiveness, security/privacy, ease of use/usability, information quality/benefits) for the evaluation of e-service quality of websites. The two of the five key dimensions (responsiveness and reliability) are of traditional retail service quality model (SERVQUAL). An advantage of eSQ model is not specific to any service industry and can be utilized with additional attributes for any specific service industry(Ladhari, 2010).

The self-service technologies are advancing these days,(Lin and Hsieh, 2011) presented SSTQUAL for the evaluation of self-service technology with different dimensions (functionality, enjoyment, security\privacy, assurance, design, convenience, customization), has limited orientation and the obtained results depends upon on those organizations which equipped with self-service facilities. Although, (Ding et al., 2011) presented eSELFQUAL dimensions (perceived control, service convenience, service fulfillment, customer service) for the evaluation of customer satisfaction and loyalty in organization.

Besides (Surjadjaja et al., 2003) also presented a model for the measurement of e service quality operations. The operations of e service quality model is divided in three groups' service marketing, service delivery and service design with twenty service quality dimensions. The dimensions presented in model has focused on the operations of service quality rather than finding a specific aspect of service quality also the large number of determinants diverts the orientation of research and provided the scattered observation about e service quality. Although, (Fassnacht and Koese, 2006)model for e service quality comprises of three high quality dimensions (delivery quality, environment quality, outcome quality) with nine sub dimensions. The model is well defined in terms of seeking information about the provided e service quality but lacks in various means such as user experience about the service quality, customization and usability. While, (Sohn and Tadisina, 2008) identifies the dimensions (availability, speed of delivery, customized communication, trust, reliability, appropriate webpage contents, ease of use, multi-functional websites) of e service quality. The determinants of (Sohn and Tadisina, 2008) model focused on the customer satisfaction with the service provided by the financial institution rather than user specific needs whereas, the security/privacy is also found as a least concern matter in this research which should be the priority for the evaluation e service quality models.

The next section of the paper contains discussion about the framework and models available for e-government service quality model.

2.3 Frameworks and Models for E-Government Service Quality

The advancements in information technology offer government to embrace changes and provide e services in government domains. In larger perspective the e service quality in government domain requires more attention to enhance the satisfaction level of user/citizen. In last decade, several authors conducted various researches to determine effective quality dimensions and measuring methods that influence the quality of e-services in e-government. The satisfaction level of user/citizen can only be evaluated by quantifying the e service quality dimensions. The risk assessment of e-government service

quality is studied by (Rotchanakitumnuai, 2008) in E-GOVSQUAL-RISK model. Another research by (AlBalushi and Ali, 2015a) identifies the evaluation of E-government service quality by using three different models; Value Measurement Model, Success or Maturity Model and eService Quality Model. The dimensions (service quality design, website quality design, and technical support, customer support quality) of E-GOVSQUAL-RISK model were utilized to found the extent of risks available for the e-government website where, the technical support dimension along with the customer support refers to the availability of technical help provided by the e-government portals.

The technical aspect of e-government portals were evaluated by (Magoutas and Mentzas, 2010)in SALT framework. While,(Papadomichelaki and Mentzas, 2011) utilized SERVQUAL as a standard and presented e-government service quality scale named e-GovQual with different dimensions (efficiency, trust, reliability, citizen Support) for the evaluation of e-government service quality. The dimensions (trust, reliability and efficiency) of e-GovQual refers to the ability to deliver the promised service in accurate way with in stipulated time, whereas the dimension citizen support refers to the availability of prompt help for enhancing user/citizen reliance on e-government service. While, (Shanshan, 2014)also presented dimensions (usability, information quality, security, responsiveness) in E-GovQual model based on the analysis of available literature for the evaluation of e-government service quality. The dimensions responsiveness and security of E-GovQual are also the part of SERVQUAL which refers to the high degree of secured services along with keenness to assist user/citizen whereas, the remaining dimensions (usability, information quality) of E-GovQual has limited scope to find the user/citizen contentment in context of e-government service quality.

In context of trust measurement in e-government,(Zaidi et al., 2014) presented the EGSTPA framework with dimensions (system quality, information quality, service quality, usefulness, citizen satisfaction, citizen trust and perceived e-government service quality) focused on the e service quality provided by the tax service providers and has restricted scope to evaluate the e-government services. The dimensions system quality and service quality of EGSTPA framework are rewording and reformulation of tangible dimension, whereas the dimensions perceived quality and customer satisfaction are extracted from empathy and assurance dimensions of SERVQUAL, which ensures that customer satisfaction can only be achieved on the basis of perceived quality of service.

(Alanezi et al., 2010)evaluated e-government service quality with different dimensions (website design, reliability, responsiveness, security/privacy, personalization, information, and ease of use) to enhance the awareness amongst the e service managers about the service quality received by the user/citizen. The scale comprises of several dimensions including reliability, responsiveness and security that are used to evaluate the user/citizen confidence in terms of providing secure service in guaranteed time whereas, other dimensions utilized in (Alanezi et al., 2010) model are reformulation and rewording and of the dimensions of SERVQUAL framework. In context of evaluation of e-government services in Oman, (Sharma et al., 2013) utilizes key dimensions of SERVQUAL to find out the perception of e services provided by government websites. The dimensions (reliability, responsiveness, efficiency, security) evaluated the secured e-government services. The research lacks apart, while considering the factor that the study is conducted only in a particular region of country instead of taking samples from different parts of country. The different attributes used (Sharma et al., 2013) has limited acceptability as they can be used only to identify the user/citizen experience about the services instead of seeking user perception about usability and degree of satisfaction received by the user.

In the context of revenue services,(Stiglingh, 2014) identified a E-SQUAL based scale with different lower level attributes (fulfillment, convenience, efficiency, system availability, reliability, assurance, empathy, responsiveness, security, incentive). The dimensions (fulfillment, convenience) refers to the degree of user handiness of successful submission of details over e government website whereas, the dimensions (efficiency, system availability, reliability, assurance) refers to the user/citizen confidence obtained by the promised services within stipulated time. Apart from the above mentioned dimensions, (Stiglingh, 2014)also suggested some other attributes (security, incentive, empathy, response) which has similarity with dimensions of SERVQUAL.

3.0 Discussion and Conclusion

The growing number of research activities in domain of e-government service quality allows researchers to identify new dimensions in order to provide better service quality to users/citizens. In this paper the authors studied all relevant quality dimensions in the area of services quality, e-service quality, and e-government service quality. SERVQUAL was used as a benchmark for being the classical and most comprehensive service quality model for which most of the available quality models in were studied for any expansions, amendment, or application to a particular domain. It was evident that SERVQUAL model remains the most comprehensive model in terms of key quality dimensions although these dimensions might slightly very as per the applied domain but they still revolve around the key dimensions proposed by SERVQUAL.

Acknowledgment

The Research leading to these results has received Research Project Grant Funding from the Sultan Qaboos University of the Sultanate of Oman, Research Grant Agreement No [SR/EPS/INFS/14/01].

Abstract

This paper presents the status of theimplementation of Measure 313 - Encouragement of tourism activities related to National Rural Development Programme (2007 to 2013) both at the national leveland at the level of the North-West region of Satu Mare, with a focusonBihor County.

Measure 313 was a highly successful onewithin theNRDP, as financing requests exceeded 87% of the budgetary allocation. Also the approved projects in the N Wregion, during the analyzed period, accounted for 26.6% of all projects approved nationwide.

The impact of using EU funds for Measure 313 is emphasized in the county of Bihor by increasing the number of rural locations in 2008-2015. In 2015, the number of rural tourism increased by 88.31% compared to 2008, as rural tourism is an activity with potential for development in Bihor county due tothe beautiful natural environment.

Keywords: NW region, Bihor County, accommodationunits, Measure 313

Introduction

The EU integration was one of the key priorities of Romania's foreign policy. As a substantial part of this strategy, Romania had to gradually adopt an agricultural policy and an institutional framework fully compatible with the Common Agricultural Policy (CAP) of the European Union. The two pillars of the Common Agricultural Policy of the European Union are supporting the market, incomes and the rural development, and their funding is through EGAF and EAFDR.

Following the creation of theNational Rural Development Programmeduring the pre-accessionand post-accession it have been noticed that a sector with great potential for development is the tourism sector supported both by SAPARD (2000-2006) and by the NRDP2007-2013. The measure which supported the development of tourism and accommodation units was 313 "Encouraging tourism activities", under the NRDP 2007-2013.

Material and Method

The paper presents an analysis of the implementation of Measure 313 – Encouraging tourism activities, related to the priority Axis III in Romania during 2007-2013, at national level in general, and the North-West region and Bihor County in particular.

The main indicators used were: financing requests granted; national level signed contracts; payments done; cancelled contracts, number of finalized contracts during period 2008 – 2014 (NRDP 2007-2013), etc.

The main method used in realizing this analysis was the quantitative method of comparison in time (2008-2014), which can be applied by calculating the dynamic rhythm of the analyzed phenomenon in the given time frame.

Data regarding the situation of tourist accommodation units in the 2007-2015 period where analyzed and processed after they were provided by the online platform of the National Institute of Statistics (NIS)

Results and Discussions

“Tourism in Romania owes much of its development to the European funds implemented by the European Agency. Continuing the success of the SAPARD program, for "Encouraging tourism activities" (313) were contracted 1533 projects worth over 216 million euros. For projects financed by this Measure were paid about 97 million euros. In the investments made by the recipients of Measure 313 there is greater weight of theleisure portion related to tourism services, which denotes an accelerated maturation of the wayto approach this sector” .(http://portal.afir.info/informatii_generale_pndr_pndr_2007_2013?amp;lang=RO)

According to NRDP 2007-2013, Measure313 "Encouraging tourism activities" is part of Axis III - "Improving the quality of life in rural areas and diversification of the rural economy" and has the overall objective of increasing tourism activities in rural areas to help increase employment and income alternatives and increasing the attractiveness of rural areas. (Source – Applicant'sguide- 6th version from March 2012, page 5).

“An important aspect of the Romanian rural tourism is represented by agro-tourism, which is usually practiced by small farm owners/rural households as a secondary activity and primarily involves women. Therefore, the support of rural tourism, in particular agro-tourism and also related leisure activities, are not only supporting diversification activities but also helps to create opportunities to better integrate women in the labour market”.(source - http://old.madr.ro/pages/dezvoltare_rurala/nrdp-consolidated-version-june-2010.pdf)

The specific objectives include:

1. creationand maintaining of jobs through tourism activities, particularly for youth and women;

2. value added growth in tourist activities;

3. creation, improvement and diversification of tourism infrastructure and services;

4. Increasingthe number of tourists and the duration of visits.(Source – Applicant's guide- 6th version from March 2012, page 5)

The structures for the reception of tourists will be in accordance with the classification rules set out in national legislation (Order of the Minister of Regional Development and Tourism no. 1051/2011 approving the Methodological Norms on the issue of classification certificates, licenses and patents for tourism amended and completions).

For new investments, modernization and extension of rural tourist accommodation structures other than agro-tourism, the comfort level and quality of services proposed by the project must achieve a minimum quality standard 3 stars / daisies.

The investments in agro-tourism have to meet the definition given in this sheet, and the comfort level and quality of services proposed by the project must achieve a minimum quality standard for one daisy. (Source – Applicant's guide- 6th version from march 2012, page 9)

A condition in accessing European funds for the development of tourist, acomponent of Measure 313, was to maintain the criteria for classifying the tourist accommodation in rural areas while taking into account the exact definition of touristic pension and agro-touristic pensions as presented in the literature:

The Tourist pension - structures of tourists reception, with a capacity of up to 20 rooms, with a total of maximum of 60 people, working in the homes of citizens or in independent buildings, which provide in special places tourist accommodation and conditions of food preparation.

Agro-touristic pensions - tourism accommodation structures with a capacity of accommodation for up to 8 rooms, operating in the homes of citizens or in independent buildings, which provide in special places tourist accommodation and conditions of preparation the food, as well as the possibility of participating in household activities or handicraft.(Source: http://statistici.insse.ro/shop/)

After analyzing the official data related to the implementation of Measure 313 nationwide within the NRDP 2007-2013, based on information provided by both AFIR and the official information that are part of the NRDP annual progress reports for the years 2008 to 2014 found to have been submitted for financing a total of 3703 applications of which 1752 were contracted, which represents 47% of all requests.Another finding was that the amount of financing applications submitted in the 7 submission sessions held in the analyzed period exceeded the amount allocated to this measure with 87,88% (303.33 million euros).

Table 1: Accomplishment indicators related to Measure 313 "Encouraging tourism activities" within the period 2008 – 2014, based upon the data provided by the Agency of Rural Investments Financing

Accomplishment indicators	No	Value (mil. Euro)	Average value (mil. Euro)	Degree of utilization of allocations
Financing requests in accordance submitted	3.703	569,89	0,15	187,88%
Total Financing Requests submitted	2.584	392,09	0,15	129,26%
Financing requests selected trough the Selection report	2.581	391,60	0,15	129,10%
Financing requested selected trough the Appeal report	3	0,49	0,16	0,16%
Contracts concluded amended with those cancelled	1.752	247,15	0,14	81,48%
Cancelled contracts	543	90,35	0,17	n/a

The value of financing contracts that were canceled during the analyzed period reached 543, representing 21% of total financing applications selected. The termination of financing was done at the request of beneficiaries because of the impossibility of co-investments due to economic conditions in the analyzed period and because of thenon-compliance with contractual terms.

At the end of 2014, a total of 202 financing contracts were completed, 2014 being the year with the most completed projects, as the period 2012-2014show an upward trend.

Table 2: The total number of projects and their value finalized trough Measure 313 "Encouraging tourism activities" based upon the data provided by the Agency of Rural Investments Financing

Year	Number	%	Public contracted value (mil. euro)
2009	0	0,0	0,00
2010	3	1,5	0,32
2011	9	4,5	1,27
2012	34	16,8	5,77
2013	64	31,7	10,30
2014	92	45,5	13,26
Total	**202**	**100**	30,92

The analysis performed on the stage of implementation of Measure 313 revealed that North West - Satu Mare was the region with the most projects approved in the whole country, with a total of 466 projects out of 1752 projects, which represented26 60% of all approved projects. North West region is made up of Bihor County, Bistrita-Nasaud County, Cluj County, Maramures County, Satu Mare County andSalaj County.

Table 3: Status of projects related to Measure 313 nationwide, those in the region NW, being based on the annual progress reports

Reference year Sessions submitting projects	Total projects submitted nationwide	Total projects approved nationwide	Total contracted projects in the region NW Satu Mare	Total contracted projects nationwide	% approved projects in the region NW Satu Mare / national
2008	273	222	48	100	48,00
2009	538	412	62	234	26,50
2010	589	445	90	255	35,29
2011	297	213	42	172	24,42
2012	2006	1292	224	992	22,58
Total	3703	2584	466	1752	26,60

The counties from the North-West region are counties with touristicpotential especially agro-touristic one due tothe natural treasures of these areas, to which we must ad customs and traditions that still retain and attract especiallyduring the holidays, but also during the full year, many tourists both from Romania and abroad.Thus isevident that Measure 313 offered an opportunityfor regional development of the area by accessing EU funds for the development of tourism and especially agro-tourism.

Bihor county has a high touristic potential due the variety of the landscape, where we can mention some tourist attractions like the Wind Cave, Scarisoara Cave, Apuseni National Park. Beside the landscape, Bihor County is rich in habits and tradition where the tourist can take part.

In the analyzed period, based on official information, in Bihor county were submitted for evaluation 186 funding applications for Measure 313, of which 110 projects were selected for funding, representing 23.6% of all projects approved by the entire region. Of the 110 projects selected, a total of 105 projects were contracted, which is also highlighted by the evolution of the number of tourist accommodation structures.

Table 4: Applications situation for funding in Bihor county in 2008-2014, processed information based on the document "Information on the status of accessing European funds for agricultural policy" developed by OFFRC Bihor

Accomplishment indicators	No.
Submitted projects	186
Selected projects	110
Contracted projects	105
Payment applications corresponding the financing contracts	58

Bihor county, a county known throughout Romania thanks to the thermal waters in the Baile Felix area, anarea that has developed a lot in the recent years, but also because of the caves in the county, that are very popular, and the mountain areas, has become a very popular tourist attraction, exploited both by existing owners of guesthouses, who sought to modernize their accommodation spaces, and bysmall businesses in the area, especially those working in the tourism field.

Between 2008-2015, the number of rural tourism accommodation units increased significantly, Bihor county is one of counties active in the North-West region in terms of European funds under Measure 313.

Table 5: Types of tourist accommodation units in N-W region, data processing according to NSI

Types of tourist accommodation units	**Year 2007**	**Year 2008**	**Year 2009**	**Year 2010**	**Year 2011**	**Year 2012**	**Year 2013**	**Year 2014**	**Year 2015**	%
Total	364	392	441	450	410	487	472	445	516	100,00
Villas	74	62	**64**	49	57	61	49	47	52	10,08
Bungalows	20	27	**27**	27	29	29	38	29	50	9,69
Campgrounds	12	11	**11**	8	**7**	7	8	6	11	2,13
Touristic pensions	58	67	**80**	100	111	138	146	137	157	30,43
Agro-touristic pensions	**200**	**225**	**259**	266	206	252	231	226	246	47,67

The Table. 5 analysis shows thatin 2015, in the North – West region,67% of all accommodation units (villas, bungalows, campsites, touristic pensions and agro-touristic pensions)wererepresented byagro-touristic pensions with a total of 246 units. If in 2007, the number of rural tourism was 200, in 2015 it increased by 20%, which shows an increased interest in this type of tourism.

On the other hand,we have identified a decrease in the number of rural tourism units in 2011 due to the economic crisis which has affected small entrepreneurs some of whom were forced to abandon the accreditation of tourist reception as required by law.

As can be seen in the NW region Satu Mare most units are agro-touristic pensions type.

It can be noticed that during 2007-2010 the number of accommodations has increased due to the support provided by Measure 313, but in 2011 the number of tourist units decreased due to crisis followed by anothergrowth in the coming year.

Fig. 1: the situation of accommodations in 2008-2015 in the N-W region, based on information from NSI

In the NW area, the Bihor county level observed a steady increase in the number of tourist accommodation structures broken down by type of accommodation units in the period 2007-2015, without noticing a decrease in the number of units in 2011 as noted previously in this region.

Table 6: Types of tourist accommodation structures in the county of Bihor, after data processing NSI

Types of tourist accommodation units	Year 2007	Year 2008	Year 2009	Year 2010	Year 2011	Year 2012	Year 2013	Year 2014	Year 2015	2015 %
Total	44	39	53	60	73	90	77	96	116	100,00
Villas	20	12	12	12	21	20	10	19	20	17,24
Touristchalets	5	5	6	7	4	4	4	4	4	3,45
Campgrounds	8	7	7	6	4	4	4	4	4	3,45
Touristic pensions	6	6	9	4	7	7	6	6	11	9,48
Agro-touristic pensions	5	9	19	31	37	55	53	63	77	66,38

The number of rural tourism in the county of Bihor represents 66.38% of total tourist accommodation units in 2015, up 93.51% compared with the number of rural tourism recorded in 2007. This shows a development of agro-tourism in the area analyzed, which is emphasized bythe large number of funding applications corresponding to Measure 313 and by the grant applications selected for funding in this field.

In regards ofcontracted projects, funded by Measure 313,theBihor county had a contract amount of 24,610,199 euros, with anamount of 15,903,589 euros of public aid. (Source - "Information on the status of accessing European funds for agricultural policy" developed by OFFRC Bihor).

In 2007, from the total of 364 accommodation units of the N-V Satu Mare, 44 units were in the county of Bihor, representing 12.08% of total accommodation units like those presented and analyzed.

In terms of the number of agro-touristic pensions,the year2015 finds Bihor county witha total of 77 units out of 246 units in the region, which represents 31.30% of the total and touristic pensions.

Table 7 : Comparative analysis by types of tourist accommodation structures, the North West and Bihor county, based on NSI data

Types of tourist accommodation units	Year 2015 N-W Region	Yeat 2015 Bihor County	2015%
Total	516	116	22,48
Villas	52	20	38,46
Touristchalets	50	4	8,00
Campgrounds	11	4	36,36
Touristic pensions	157	11	7,01
Agro-touristic pensions	246	77	31,30

Conclusions

The Measure 313 "Encouraging tourism activities", with a financial allocation of 303,33 mil. Euro for the period 2007-2013 in Romania, was a measure that attracted a high amount of interest from the potential beneficiaries, the amount requested by applications submitted for evaluation and selection during 2008-2012 exceedingby 87% the amount allocated;

North West region Satu Mare was the region with the most development projects approved out ofthe 8 regions with 26.6% of total approved projects;

The investments in rural locations (modernization / construction) and recreational structures were investments with the highest share of total investments funded by Measure 313 in the analyzed period;

Bihor County was one of the counties active in funding applications for Measure 313 with a total of 186 projects submitted, out of which a total of 105 were contracted projects;

Between 2008-2015, the number of agro-touristic pensions in Bihor county had an upward trend from 9 pensions in 2008 to 77 agrotouristicpensionsin 2015, with a significant increase of 88.31%;

Codes of Conduct in Top 100 Czech Companies

Jaroslav Kacetl, Faculty of Informatics and Management, University of Hradec Kralove, Hradec Kralove, Czech Republic, jaroslav.kacetl@uhk.cz

Blanka Klimova, Faculty of Informatics and Management, University of Hradec Kralove, Hradec Kralove, Czech Republic, blanka.klimova@uhk.cz

Abstract

The paper looks into whether or how top Czech companies employ codes of conduct. More specifically, whether or not 100 top Czech companies ranked by Bisnode – EVA (Economic Value Added) TOP 100 ranking – have an easily accessible code of conduct on their company websites. The incidence of codes of conduct on the companies' websites is determined and the found codes of conduct are studied and assessed according to their characteristics by means of text analysis. The basic questions ask whether it is easy to find the code of conduct on the company website, if it is original, what its layout looks like, how long and detailed it is, whether it is divided into chapters and easy-to-use, or what interesting features it has. The code of conduct can be an instrumental gauge, which should help the authors assess the position of business ethics in top Czech companies.

Keywords: Code of Conduct, Business Ethics, company website, top Czech companies

Introduction

The current world shows signs of a paradigm shift. There are happening unparalleled changes like the advancement of new technologies, in particular ICT. Globalization generates new challenging problems, different groups of people meet and do business with each other. People of different backgrounds often lack any common set of rules to follow in order to understand each other and be able to cohabit and work together.

In this environment, the importance of finding a commonly acceptable set of rules is high on the agenda. In business environment, one of the most important way how to fill the vacuum is to implement company codes of conduct and make them available to all stakeholders and the public. The code of conduct may take different forms. It can either be a short list of essential requirements related to the job in question, or it may be an elaborate document describing in detail how one should behave when they encounter a problem issue at work. High-quality codes of conduct set rules and ideals of the company and promote its vision and philosophy. To date, few authors have done research in this area in the Czech Republic. Canik (2007) comments a Study of Code of Conduct Application. This research was done by Transparency International and the University of Economics in 2005 and 2006. It looked into the incidence of codes of conduct in Czech companies and institutions. It also studied the relation between the company size and origin and its having an original code of conduct. Last but not least, this research aimed to find out the length of the company codes of conducts and whether they were public or meant only for the employees.

This paper looks into whether or how top Czech companies employ codes of conduct. The basic questions ask whether it is easy to find the code of conduct on the company website, if it is original, what its layout looks like, how long and detailed it is, whether it is divided into chapters and easy-to-use, or what interesting features it has.

Methodology

This research was done in April and May 2015 as a part of subject named Business Ethics at the Faculty of Informatics and management, University of Hradec Kralove, Czech Republic. Twenty

students who attended this subject were asked to study company websites of 100 top Czech companies ranked by Bisnode – 2012 EVA (Economic Value Added) TOP 100 ranking, which was the most recent ranking they were able to find of the Internet (Stepanova, 2013). Each student was to study five company websites. They should look for a code of conduct and answer several questions. The most important one was whether 100 top Czech companies ranked by Bisnode – EVA TOP 100 ranking – have a code of conduct on their company websites. If so, whether it is easily accessible, how long it is, what it looks like, whether it is easy to understand, and what is interesting about it. Then, the gathered information from all seminar works was collected and assessed in order to evaluate results.

This study was done as a follow-up to research done in 2014 (Kacetl and Semradova, 2015). The 2014 pilot study used the 2013 EVA TOP 100 ranking and had two main directions. First, it studied the websites of twenty companies. These companies were selected at random – they only had to have their code of conduct on their company website. Second, the pilot study analyzed codes of conduct (if there were any) of the top 20 companies according to the 2013 EVA TOP 100 ranking. The available codes of conduct were thoroughly studied in order to find answers to several questions. Among other things, the pilot study determined that the incidence of a publicly available code of conduct on the websites of the above mentioned companies was 80%.

The mentioned ranking by Bisnode uses the indicator EVA (Economic Value Added), which provides information whether companies appreciate or depreciate financial means of both shareholders and creditors. The higher the absolute EVA is, the greater competitive advantage the company in question has. EVA is a unique evaluating tool, which is capable of assessing the efficiency of the company. Bisnode provides digital business information in Europe that helps companies make the right business decisions, minimize business risk and increase sales.

The survey

The survey was done by students, which had both advantages and drawbacks. Among the advantages belongs the fact that students are usually used to searching information on the Internet. Twenty students, or survey workers, studied 100 websites. As a result, each survey worker was to study only five different websites, which means they could study them carefully and in detail. Moreover, the survey was done very quickly and there was even time to contact some companies. It happened only in case the survey workers did not find any code of conduct on a particular company website. In such cases the survey workers were to send an email enquiring about the existence and whereabouts of any company code of conduct to company representatives, whose contacts where published on the website.

On the other hand, there were some disadvantages, too. Although all survey workers were given the same template of seminar work, the collected papers sometimes differed from the expected format. In such cases it was necessary to look for some information again. Another problem results from the fact that it is subjective to evaluate whether it is easy to find some information on a website. Some students may orientate themselves on websites much easier than others, or they may be only lucky to quickly find the information they look for.

The survey also proved that some information is difficult or impossible to find out. Namely, it was sometimes impossible to determine if a particular code of conduct is original or adopted. In other cases, the same code of conduct – created by a parent company – was used by several subsidiaries. The survey worker also pointed out that some of the companies ranked among the 100 top Czech companies – among others OBI, Samsung, Hyundai – have their headquarters and owners outside the Czech Republic, which makes the adjective Czech rather strange to use. On the other hand, Bisnode take into account all companies active in the Czech Republic. All in all, the survey pointed at several new questions it would be necessary and useful to ask.

Results

The basic survey questions were as follows:

- How many top Czech companies have their code of conduct easily accessible on their company websites?
- Is it easy to find the code of conduct on the company website?
- Is the code of conduct original or adopted?
- How long and detailed is the code of conduct?
- Is it easy-to-understand?
- What interesting features does the code of conduct have?

The collected data concerning the above mentioned questions suggest the following results. Concerning the first question (How many top Czech companies have their code of conduct easily accessible on their company websites?), according to the survey, 60% of the 100 top Czech companies have a code of conduct on their company websites. In the remaining 40% of cases survey workers were unable to find any code of conduct on the company website and the company did not react to their further enquiry. This does not necessarily mean that these companies do not have any code of conduct or another type of business ethics policy. Generally speaking, the most successful Czech companies have codes of conduct published on their company websites.

The second question (Is it easy to find the code of conduct on the company website?) might be rather difficult to measure precisely as it is subjective to assess if it is easy or not to find a code of conduct on a particular company website. Nonetheless, according to the survey workers, in 36% of cases it was easy to find the company code of conduct on the corresponding website. According to the survey, 24% of companies have difficult to find codes of conduct and the remaining companies (40%) may not have any code of conduct at all. At least, the survey workers did not find them. As a result, about one third of the surveyed companies have easily accessible codes of conduct.

The third question (Is the code of conduct original or adopted?) proved be difficult to answer as it is unfortunately almost impossible to find out whether or not particular codes of conduct on company webpages are original. The answers given by survey workers were based either on their personal opinion, or they responded that they did not know.

Collected responses to another question (How long and detailed is the code of conduct?) were used to assess the length of codes of conduct. The pilot study done in 2014 determined that the length of codes of conduct can divided into 5 categories (see Table 1). These categories were based on the number of pages, including pictures and other features and the page layout of codes of conduct. Therefore, in some cases a two-page document with pictures and other similar may be, if the number of words is taken into account, shorter than a one-page document. Another important factor is the fact that several companies share the same code of conduct as they belong to the same parent company. This happens in several cases, for example Continental HT Tyres (3rd place in the 2012 EVA TOP 100 ranking) and Continental vyroba pneumatik (5th), or RWE Distribucni sluzby (50th), RWE GasNet (52nd) and RWE Energie (99th).

Table 1: The length of codes of conduct

Category – No. of pages	No. of codes of conduct
1 page	17
2-10 pages	20
11-20 pages	9
21-30 pages	5
31 or more pages	9

Table 1 shows that more than a third of all 100 companies (37%) have codes of conduct up to 10 pages – 17% have only one-page documents, another 20% use a bit longer ones. If we take into account that another 40% of companies did not have, according to the survey, any code of conduct, it is clear that most companies do not have elaborate codes of conduct. On the other hand, almost one quarter of all companies (23%) have codes of conduct longer than 10 pages and 9% of them have a code of conduct longer than 30 pages, which makes it a really detailed document.

The answers to the following question (Is it easy-to-understand?) were also quite difficult to assess as it is rather subjective to decide on this issue. Nonetheless, if one focuses on languages of codes of conduct, one find out that it is not a rule that a Czech company (or at least a company active in the Czech Republic and having Czech-speaking employees) has a Czech code of conduct. In some cases the surveyed companies have only English (Linde – 22nd place, CABOT – 55th, ITT Holdings – 97th) or German (OBI – 86th) codes of conduct, which is not a good practice as all employees should be able to understand their company code of conduct.

The findings based on responses to the last question (What interesting features does the code of conduct have?) showed that several companies have elaborate codes of conduct. Some of them are not in Czech, though. The examples of well-written Czech codes of conduct can be found on the websites of ČEZ PRODEJ (6th place), Phillip Morris ČR (7th), Zentiva (37th), which was adopted from the parent company sanofi Aventis, Vodafone (62nd). Other thoroughly made codes of conduct are written in English – Linde (22nd), CABOT (55th), ITT Holdings Czech Republic (97th), or Samsung Electronics Czech and Slovak (98th). Very interesting is the code of conduct of British American Tabasco (58th), which looks like a presentation with 25 images. The above mentioned codes of conduct could serve as examples of good practice.

Conclusion

Codes of conduct should help promote fair practices in business, honesty and respect for others as well as the law. They improve the quality of work, as well as health and safety. They treat various conflicts, corruption, and much more. Codes of conduct also help the public to assess the company, help prevent unethical and unfair behavior as well as discrimination at workplace. They upgrade the image of the company, make it trustworthy and they also act as the basis for a remedy in case of faults.

The authors of this contribution will continue in studying codes of conduct. The study drew attention to some interesting facts that can be studied in the following years. It shows that there is still much to improve in this area in top Czech companies even though most successful Czech companies have codes of conduct placed on their company websites. Nevertheless, only one third of top Czech companies have easily accessible codes of conduct. The length of these documents suggests that companies do not care much as 37% of companies have short codes of conduct and another 40% of companies may not have any code of conduct at all. On the other hand, 23% of companies have at least 10-page-long codes of conduct and 9% have long and detailed codes of conduct. Some codes of conduct are only in foreign languages like English or German, though. This is a problem as all employees should understand their company code of conduct. Fortunately, there are several companies with really high quality codes of conduct. These companies may act as examples of good practice.

Open Innovation in Big Companies: An Empirical Study

Cândida Silva, School of Management and Industrial Studies, Polytechnic Institute of Oporto, Vila do Conde, Portugal, candidasilva@eseig.ipp.pt
Center Algoritmi, School of Engineering, University of Minho, Guimarães, Portugal
Isabel Ramos, Center Algoritmi, School of Engineering, University of Minho, Guimarães, Portugal, iramos@dsi.uminho.pt

Abstract

Innovation is recognized by academics and professionals as essential to enhance the competitiveness of organizations and foster their growth. Traditionally, innovation is seen as going mostly just within the company. However, the increasing availability and mobility of knowledge labour, the development of Internet and venture capital markets, as well as the easier to widen the scope to possible external knowledge providers, have weakened the effectiveness of traditional innovation systems (Chesbrough, 2003). Thus, open innovation concept is presented with the essential premise of opening organizational boundaries. The underlying idea is based on the assumption that in a world where knowledge is distributed, companies should not rely solely on its own research and development, but open up their boarders to external knowledge. Therefore, the aim of this study is analyse innovation strategies and practices developed by medium and large companies in order to understand how they enhance innovation within the company or other partners or companies they work for, and what are their perspective on crowdsourcing phenomenon as a practice to potentiate the introduction of innovation in companies. An empirical study was conducted following the Grounded Theory method to collect and analyse empirical data. The results show that companies are starting using some external knowledge in their innovation process though they still have some bias in introducing strategies that uses the global network. At the end of the paper the results are discussed and some future research directions presented.

Keywords: Open innovation, Crowdsourcing innovation, Innovation process.

Introduction

Nowadays, companies are living in a hyper-competitive and accelerated market environment that requires short response times, more accurate responses and wider exploration of potential opportunities. Changes in the competitive panorama, along with the recent economic and market pressures, increase the need for organizations to reduce costs, improve their margins, generate new sources of revenue, and bring product offerings and/or services faster to market (Prandelli, Sawhney, and Verona, 2010).

The evolution of the Internet and of the Information and Communication Technologies has highly contributed for companies to have easier access to information, often much more information about their customers, suppliers, employees, competitors, and other decision makers. However, companies still have to analyse and explore all that information to find potential opportunities, evaluate it and make decisions in accordance (Bonabeau, 2009).

The competitive importance of innovation, and the risks and difficulties in its management are recognized by professionals and academics (Tidd, 2001; von Hippel, 2005). A key element arises from the fact that innovation is essentially the combination of different types of knowledge, particularly tacit and explicit knowledge (Nonaka, Keigo, and Ahmed, 2003; Prandelli et al., 2010; Tidd and Bessant, 2013), and this knowledge is often available outside the organization's boundary (Chesbrough, 2003).

In this sense, Chesbrough (2003) introduced the concept of open innovation as an essential premise for organizations open their borders to external knowledge. This concept is based on the assumption that in a world where knowledge is distributed, companies should not rely solely on its own research and development. Therefore, Chesbrough defines open innovation as the deliberate use of knowledge inputs and outputs in order to accelerate internal innovation, and expand use of external innovation

markets, respectively. Thus, open innovation is a paradigm that assumes that organizations can and should use external and internal ideas as well as access to the internal and external markets, as a means to achieve competitive technological advances (Chesbrough, 2006). Thus, the concept involves achieving new innovation sources outside the organization, which includes two main dimensions: the creation and capture of value to the organization (Chesbrough, 2003, 2006). Value creation is the development process from an idea to a new product or service. Open innovation increases the likelihood of creating value as it exposes the organization to additional sources of ideas and Intellectual Property (IP) that can be used for the development of new products or services.

Capturing value involves creating resources, assets, or a position that allow the organization to develop a competitive advantage. Open innovation increases this potential since the organization is open to benefit financially from ideas and IP from inside or outside the organization. In this sense, the organization is willing both to buy and to sell ideas and IP.

Open innovation processes

Chesbrough (2007) identified two types of knowledge flows between an organization and its external environment: Inside-out (or Outbound) - which corresponds to the knowledge developed by the organization and made available to other organizations; and Outside-in (or Inbound) - knowledge developed in the external environment and which is integrated and embedded in the organization.

Gassmann and Enkel (2004) identified another innovation process structure adopted by companies that follow an open innovation strategy: Coupled. The three open innovation processes structures are shown in Figure 1.

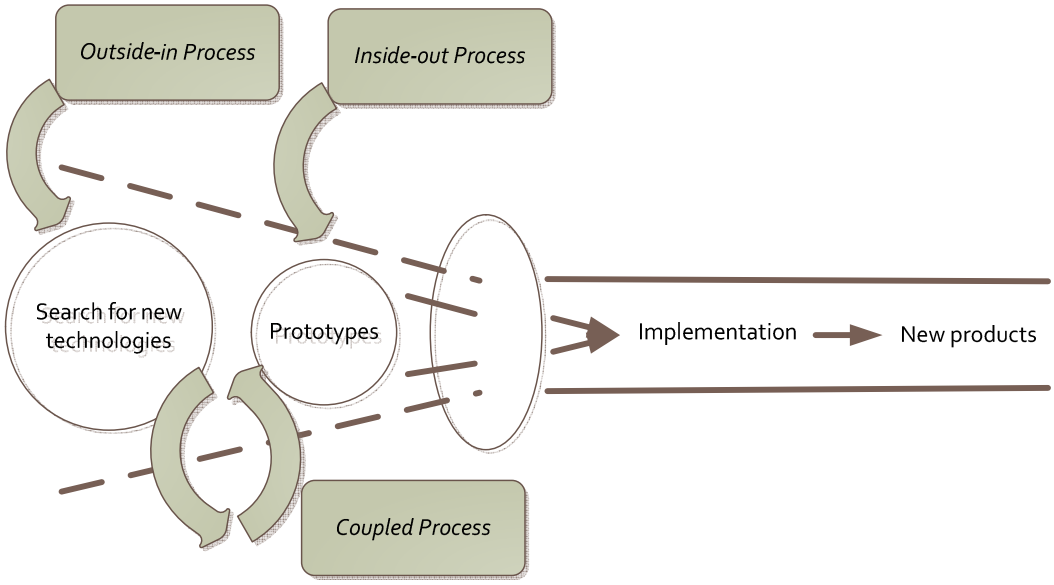

Fig. 1 – Open Innovation Processes (adapted from (Gassmann and Enkel, 2004))

Outside-in process the company's knowledge is added with external knowledge obtained by integrating knowledge of its suppliers, customers and other external actors. The external knowledge is achieved by consulting innovation forums, development of innovation initiatives with industry partners, the acquisition of IP or the investment in the creation of knowledge in collaboration with external actors (Gassmann and Enkel, 2004). In this process the organization invests in cooperation with its suppliers and customers, and in external knowledge integration. Companies that adopt this process are usually characterized as being poorly developed technologically in the industry in which they operate, and therefore intend to adopt technology from the market. However, they hold a lot of knowledge and experience in the industry, with highly modular products, and therefore also often act as mediators and/or creators of knowledge to large companies (Gassmann and Enkel, 2004). This process is composed by activities like timely integration of suppliers, technology development in collaboration with customers, external knowledge search, link between organization and supplier of

knowledge, evaluation and integration of knowledge by licensing of technology, and/or acquisition of patents.

The **Inside-out process** is characterized by the placement of ideas and technology developed internally in the market through the sale of IP and the availability of new technologies, transferring ideas and concepts to other companies.

Companies that adopt the Inside-out process are characterized by having a strong capacity of research and development, and therefore want to reduce the fixed costs of R&D by establishing standards in the market, through the transference of technology and concepts developed internally for other companies. Thus, these companies will profit by licensing IP and/or sale of technology, transferring ideas to other companies. The commercialization of ideas in different industries, and thus applying the open innovation process Inside-out, can significantly increase the company's results. Innovations between industries emerge when companies integrate or license technology that is already established in their industry, but it is new for other industries (Gassmann and Enkel, 2004). This process begins with the task of identifying the knowledge area to explore and the consequent development of internal and external opportunities for providing such knowledge in the market. Follows the activity of finding applicability for technologies in other industries and its placement on the market, and by that way, introducing new ideas, concepts and standards in the market. Then, it is performed the activity of linking the selling organization and the potential buyers. The selling organization performs, internally, the evaluation of proposals and selects the most advantageous one. Finally, is realized the activity of patent sales and/or technology licensing.

The **Coupled process** combines the Outside-in activities (get external knowledge) with the Inside-out (put ideas and internal IP on the market) through alliances and collaborations with strategic partners' networks. Organizations that adopt this type of process cooperate with other organizations in strategic networks. To cooperate successfully it is necessary to receive and share knowledge, so the interconnection between processes Outside-in and Inside-out are key elements of this success. The interconnection and union between organizations can be a strategic option achieved, for example, with alliances where the IP is shared. Cooperation refers to jointly develop knowledge through links between specific partners, such as consortia of competitors, suppliers and customers, joint ventures and alliances, and universities and research laboratories (Gassmann and Enkel, 2004).

In this regard, a study was conducted with medium and large Portuguese companies operating internationally, and that have R&D department, in order to understand what innovation practices and transfer of technology are developed by these companies, how they enhance innovation within the company or other partners or companies they work for, and what are their perspective to the crowdsourcing phenomenon as a practice to potentiate the introduction of innovation in companies.

This paper is organized as follows: in the next section are presented the methodology used to realize the empirical study, namely the sample characterization and the description of process and data analysis. The next section presents the results obtained, and the paper ends with a section of discussion of results and main conclusions of the study.

Methodology

This study was conducted according to the interpretative research paradigm, flowing the orientation and evaluation principles of Klein and Myers (1999) . The companies were analysed in order to understand the way they do their innovation processes and to induce how crowdsourcing can be used as a strategy and practice for this type of companies to enhance their innovation. Thus, the research strategy was to induce an explanatory model of knowledge of the practices and experiences of organizations that may foster innovation. Therefore, the study was conducted under the orientations of the Grounded Theory method, since it allows to induce a set of concepts and relationships between them from the empirical data collected (Charmaz, 2006; Urquhart, 2013).

Participants

The participants of this study were five big companies with headquarters in Portugal and with business aboard. The companies are classified as medium or large companies once they have, in medium, over 300 employees. It were a condition to select the company that it have a R&D

department or structure and well defined process of R&D because we want to analyse the procedures and activities developed to potentiate innovation within the company. Therefore, the participants, from each company, in this study were the head of the R&D department or the responsible of the innovation process. Two of the companies have its headquarters in the north region of Portugal and three of them have it in the centre region of Portugal.

Procedure and Data Analysis

The participants were contacted by email, where it was explained the objectives of the study and the conditions to participate in it. The companies that accepted to participate in our study signed an informed consent form where the objectives and conditions were explained. It was realized semi-structured interviews, in person, in the office of the participants, and with audio record. The average length of the interviews was 50 minutes, with the smallest took 40 minutes and the largest duration of 86 minutes. Despite the cost and time required to transcribe interviews, the arguments in the literature for the importance of performing this task were decisive, so all the interviews were transcribed by the researcher. Besides, it was not considered the possibility of using outside professionals to carry out transcription, mainly because it is considered that in the process of transcribing the investigator has already started analysing the information collected. Thus, all interviews were transcribed in full, verbatim, that is, word for word, being reviewed at the end. The transcripts of the interviews were made in Portuguese and took an average of 6 hours per interview, and with an average review time of 2 hours and 30 minutes per interview. Also, all the procedure of coding and analysis were made in Portuguese.

The data collection and analysis were deliberately interweaved, i.e., theoretical sampling, so that subsequent questions could be revised to reflect and check the emergent categories. Theoretical saturation was used to compose the sampling. The data were analysed according to Grounded Theory procedures (Charmaz, 2006; Urquhart, 2013) using NVivo 10.0 software.

To ensure the validity of the analysis and the coding process, a second researcher was consulted as auditor (an independent researcher that discuss and validate the categories) throughout the entire data analysis process to assist the primary author by challenging ideas and assisting in the construction of the categories. The main results are presented in next section.

Results

In order to analyse and understand the innovation procedures and activities developed by companies semi-structured interviews were conducted. The analysis of these interviews revealed the model represented in Figure 2, composed by the following integrative categories: Ideation, Roadmap, Project, External Knowledge, Process, Client Relationship, Partners, Knowledge Management and Intellectual Property.

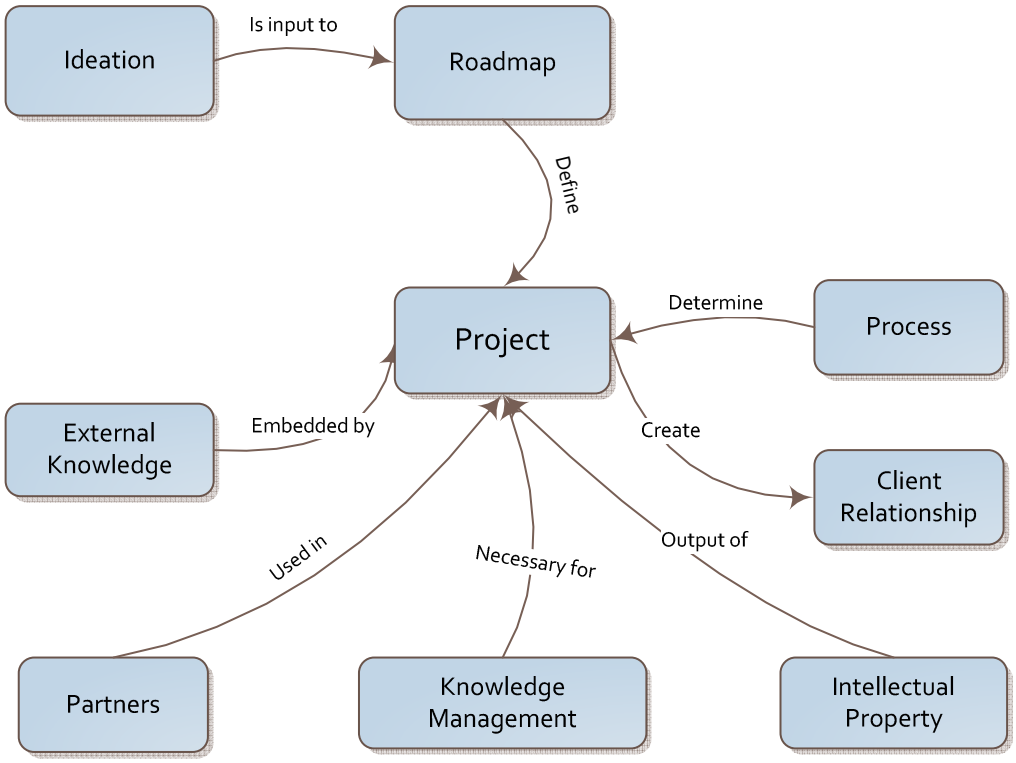

Fig. 2 – Categories and relationships schema

A more elaborate description of the results is presented is the rest of this section with participants' transcriptions to illustrate and facilitate understanding.

The **Roadmap** defines essentially the project development plan, i. e., which projects should be included in the business plan of each year. This plan includes mainly the evolution of products already marketed by companies with the introduction of small innovations, such as new features or changes to existing features. However, this plan may also consider conducting "exploratory projects" of new concepts or products. Such projects are usually developed in collaboration with universities and research centers or laboratories. In the roadmap are introduced ideas that have been considered feasible to be developed, as well as bug fixes or improvements to products that have been identified. Thus, this plan will define the projects to be developed that year, and what are the specific characteristics of each project.

The concept of **Ideation** emerge from a set of activities and actions undertaken to foster the introduction of innovations in products, the emergence of new products or new uses of products, either within the same market or to different markets. Therefore, this category is defined by the grouping the following selective codes or subcategories: Ideation Process, Strategies, and Difficulties.

The subcategory **Ideation Process** can be organized into four subsequent phases: (1) the timing of the ideas generation, which can happen in different ways, according to the strategy pursued by the company; (2) the selection and organization of a list of ideas of interest to the company's strategy; (3) assessing the viability of the selected ideas; and finally, (4) the selection of one or more ideas, which are viable of being implemented, are integrated in an exploratory innovation project or incorporated directly into a product.

The strategies used to enhance the generation of ideas and drive the organizational innovation process is organized in internal activities and actions that may involve external entities such as customers, partners, and universities or research laboratories. In internal strategies there are committees or working teams across the different departments and projects developed by the company which have a comprehensive and integrated view of the all organization's activity and which enhances the sharing

of knowledge and experiences between different projects, as stated "*…they [committees] have a more horizontal framework and more focused on the area of user experience and innovation …*", "*…these committees and divisions said, and this division is transversal, aims precisely this, when you are creating projects say «look that you are trying to use in this project has been used in that other project*» …". In this sense, it is promoted an organizational culture for innovation, carrying out actions to foster the creativity of teams, covering competitions for ideas, using platforms of ideas management, adopting a collaborative internal portal, flexibility in product development processes and with the introduction of new working methods. Examples of this are "*…although we have a structured development process, we create the necessary space for each person involved in the process can also innovate. We do not create requirements and working methods too hard to inhibit the creativity of people ... we give quite space so that people can experiment and introduce new working methods, new ideas, new approaches to problems…*", and "*…We have an idea management system, internal of the company's group ... But we also have an internal tool for collecting ideas. ... ideas management tool, but there would be more new projects ideas. When the ideas are for a concrete project, i. é., are ideas that arise, there are other tools for this purpose, but more dedicated to the management of the project itself, that is a transversal tool of the company's group…*".

With regard to **Strategies** for capturing external ideas there are activities like the development of exploration projects in collaboration with universities and research centers, and the use of committees or advisory teams that integrate the company's employees and external parties, such as clients, providers, and the regulatory authorities. Another type of external actions results from the use of the platform for communication with customers and partners, where they can suggest new features to products and launch ideas for new modules or products, as this statement exemplifies, "*…There is a platform for product management, ..., which is a portal where any customer or partner can give suggestions for product development, which are then evaluated by the product management team.…*". In the Difficulties subcategory was reported the difficulties to efficiently manage the platform of ideas and suggestions of customers and partners, as stated "*…our only difficulty is the excess of ideas, and the segmentation between what is the need for a customer and what is important to many. And then reconcile it with no explicit needs of customers who are often even more important than those which they can express. Often the customer only has the notion of their needs when we have already put it in the product and he starts using it. And then he says, «this is fantastic, it was exactly what I needed and didn't know»...*".

There were indicated other activities that are being planned to develop by companies, such as the creation of a user experience laboratory, where customers are invited to test and review the products and their features before they are launched on the market, as stated "*…we have people to do user experience tests, in specific screens and features, in which we are not sure it operation is the most easy way, and then we create labs to make that kind of assessment. We are implementing this right now, although still at a very earlier stage...*"; and the release of a innovation crowdsourcing platform targeted to university students for the development of small challenges in software development. The implementation of this initiative found some resistance inside the company, which delayed its release, as mentioned "*…first we need to have internal challenges. For now it is not being easy. The first battle is to overcome the internal barrier, which is people, directors, have to use the platform, and have to write challenges. If you do not have challenges, it won't work! This seems a small barrier, but it's too big.*".

The **Project** category is characterized by having an aim, project team, development process and a type of project. Therefore the aim of the project can be fix a bug or to improve some product feature or module or it can be an "exploratory project" that arisen from one or more ideas that were evaluated as feasible and integrated in the projects roadmap. In this last kind of project, sometimes, are involved universities or research centers or labs, for example, "*…we have a set of projects that we release every year, where sometimes we test concepts. When we more "different" ideas, we do small projects with universities to analyse and test the concept...*". In this projects, the client of the project is internal, i. é., the team or department responsible for the product management. Although the client is internal, these companies has costumer that influence the development of product in an indirect manner.

Therefore, it emerges the category of **Client Relationship**. In this concept is defined by the way contacts are established and the management of client expectations. The contacts are mainly by networking or by the presentation of product and its features to clients. The issue of managing client

expectations of the management and the need of its collaboration in the identification of product needs is referred by these companies as very relevant. These collaborations are achieved essentially by the communication channel with the customer, which involves mainly the assessment of customer satisfaction in a platform, where it is recorded customers suggestions and complaints, and the state of follow-up of each one. Examples of this are the statements, "*…is a portal where any customer or partner can give product development suggestions, which are then evaluated by the product management team .... at anytime you can see the state of your request. You can whether it is being analysed, or if it has been considered and will not be implemented, or are planned to be implemented or already in implementation or if it is expected to be implemented in a specific version...*". In some cases, clients and partners have a direct involvement in product development, as stated, "*…There are cases also where we involve ... partners and customers and they are beta-testers of products and use, before the product is released to the market, they use in real life environment versions of the product that are not yet final versions.*".

The **Process** category gathers, subsequently, the categories of Discovery and Delivery. In the **Discovery** there is the identification and selection of people that will compose the project team; the identification of a problem or innovation opportunity, and the analysis of that problem. The project team is, usually, composed by employees of the company, but it also can have outside specialist or other partners. In this matter, it was mentioned by some companies the usage of systems that helps to manage employees skills, as a mean to facilitate the task of selecting the more adequate skills and employees for each project. For example, "*…a tool ... that has the skills map ... we ask employees to go to this map and to register what is the proficiency they have, and the skill or skills they have ... when we have a project, we define which are the profiles and skills we need. We can define the profile or profiles of employees we want to that project ... setting it, this system gives me who are the employees who best map that profile and therefore, in principle, I should select these persons…*".

The identification of the problem will define the aim of the project and, therefore, results of the ideation process or of the identification of any bug or improvement in the product. The analysis of the problem involves the evaluation and decision of including or not the idea or product improvement in the product, and what is the best moment or product version to do it. The collaboration with specific costumers usually happens to support the decision of introducing modifications in products, by testing it before the release of the final version. After deciding to modify product or develop a new product, is unleashed the **Delivery** phase. In this category takes place the design and implementation of the solution and the knowledge transfer to the client and partners. The design refers to searching and gathering internal and external information, standards and regulations, best practices, and other technical or functional information that can be useful to product development. An example of this task is, "*... gather information for our work is a lot with customers ... among standardization organizations, where are others like us, and discussing standards we will see how technology is evolving, and so we will also see how our solutions are evolving, and we will updating our solutions with these technological developments, and also some things here inside, that is, we also know the customers and knowing the technology...*". In the implementation phase was highlighted project evaluation meetings, as moments to share knowledge and experiences with the project development; the active participation of the client, sometimes even in the share of development costs; and the usage of tools to support the management of product development by allowing sharing and reuse of modules and software packages, as mentioned by "*…all the development process is supported by tools. One of the things that we are investing is in creating software packages...*".

Knowledge transfer is made by implementing strategies like product training of users, client experimenting and testing the product and with the installation and operationalise of technology in client environment. There were also references to an online platform that gathers documents and reports to support customer in product usage; conducting training using e-learning platforms; and the certification of partners in specific products, as a way of training partners to deliver and support other customers of their products. Some evidences of this are, "*…are employee of partners who have been trained by [company] and necessarily have to go through a set of certification exams that allow this partners to have certain collaborative status...*", and "*…There is a documental platform that has all the information on the product ...Which all the customers or partners have access...*". Besides that, these companies also assimilate knowledge by themselves through the meetings, networking and collaborative partnerships that they develop, namely with universities and research centers.

The **Partners** category confirms the need of a strong relationship between companies and partners as a way to have easy access to specialized skills and of being updated with the last technological developments. Examples of this are, "*…we have a partnership network assembled and so far it has lived up to our expectations and has responded to our needs…*" and "*…we have a good relationship with universities, where basically we get specialized skills…*". It was also enhanced the importance of product certification of partners and the management of partners in terms of being able to easily identify the right skills of partners in each moment and for each project, as mentioned, for example, by "*…we have internal processes of technological surveillance, and of management of partnerships. We have it all. And that will then feed, when there is the definition of the project team, it comes from there some of the inputs…*".

The category of **Intellectual Property** is explained with strategies of intellectual property protection such as the settlement of confidential memorandum with partners and customers at an earlier stage the establishment of a contract; recourse to the use of product licenses; and the usage of general terms and conditions for the participation in platforms of suggestions and ideas. It was also reported the usage of patenting when there is a new concept to be implemented by software and hardware, and situations of sharing intellectual property with partners, as mentioned, for example, by "*…it has happened in some cases, and usually happens with R&D institutions, for example those projects I spoke earlier, smaller ones to explore things, then the property is shared. When we register a patent, it is usually shared by 50%...*". Finally, it was mentioned the situation of the intellectual property belonging to a particular customer for a defined period of time, "*…cases where is needed to reserve intellectual property, we do so with a timing set. That is, we define in customer contract that for example a specific functionality was developed exclusively for that customer and we cannot sell or use it in a given period of time. However, apart from some exceptions in which the customer gets significant competitive advantages being the exclusive owner of some functionality, this isn't something that is much desired by our clients because they knows that when we develop exclusively for them the cost of the project is much higher…*".

In the category of **Knowledge Management** are referred strategies of managing internal knowledge online, by using internal portals, forums and wikis to systematically gather projects and corporation information; face-to-face sessions, with project evaluation meetings and lessons learned forums; the rotation of employee through projects in order to acquire skills and potentiate information sharing in informal meetings among employees; and the production of technical documents, reports and manuals of projects and email exchange. The following statement can exemplify this category "*…closing the project with the lessons learned session, registering the positive and negative aspects, an assessment. And we have the portfolio of projects closed and stored, and that are available for a while to be reused in other future projects.... We try to somehow spread this knowledge throughout the organization with workshops or regular meetings of the development teams and regular meetings with leaders of the development teams of the different projects in development to share experience and points of view...we also have the informal meetings in coffee and lunch breaks, which also promotes the sharing of information between projects…*". In this category also appears some concern with the standardization of methodologies and with the usage of tools to support knowledge management and sharing, being mentioned the company's certification for Innovation, Research and Development, as well as the implementation of a tool, like a social network, aiming to promote socialization and sharing of experiences among employees, and the adoption of specific tools to potentiate knowledge sharing, such as of management of product development, of training in e-learning, of collaboratively develop and sharing of project documents, and of management of ideas. Some examples are stated in "*…a market tool, open source, which allows us, which is a tool where we can define issues. When I am developing a project, I will create issues that are being closed as they are solved... each project that we have, has associated with it a site in a sharepoint where all documents are placed and shared. In some cases it is shared through the company, which they have available the project documents and usually a wiki associated in which all people of the project can contribute in this wiki. For each project, the wiki works as a way to exchange and share knowledge, opinions on the project....We introduced recently this type of tools, including the user portal, developer...with the philosophy of social network. This is a tentative to people stop sending emails and start to communicate via this portal…*". Although, it was also reported some difficulties in sharing knowledge between projects, mainly related with some resistance of employee in adopt this kind of tool, as stated in "*…I think this is not easy [knowledge sharing between projects]. I think the wiki has had some membership, the sharepoint too. ... But what I notice is that there is some*

resistance to all these things. For example, the sharepoint has all sharing facilities, but in many cases what we noticed is that what most people do is close the project sites. The project area is closed just to the project team. This limits later when we need to access the information, it does not exist. Or rather, exists but is closed…". Other strategies are being planned towards the management of the internal knowledge and absorption and assimilation of external knowledge, in particular the development of an organizational culture of service, transforming the product into a service and taking advantage of current opportunities in the cloud, as well as considering the technological advances which are increasingly enhance the usage of the cloud, as stated in "*…We have seen the spread of solutions based on cloud, which extends the number of opportunities, not only in terms of geography but also in terms of business models and in terms of target audience…*". It was also referred strategies to develop product abstractly and with modules which enhances its reuse in other markets, as well as the application of existing technology in new concepts, as exemplified by the references "…other clients have said, it is interesting to audit the stores. Audit stores is an internal task, they have checklists to check with yes or no. And from internal audit it passed to maintenance tasks, because you can check the bulbs, to count how many are damaged and things like that, and it all went to the interventions …".

Finally, in the category of External Knowledge, knowledge from outside the company is embedded and absorbed in projects and businesses mainly by collaboration with external partners, by using external experts like universities, research centers and laboratories, and also with some more specific activities like the consultation of customers and specific communities through Internet calls, such as university students. There are also presented the advantages of absorption and assimilation of external knowledge through access to a diversity of people and skills, integration into networks of specialized companies and complementarity of skills between companies.

Discussion and Conclusions

The main concept enhanced in this study is the concept of **Project**, everything happens around it. However, the projects are of internal nature to the company, in the sense that are associated with the products that companies sell either in developing products already in the market or developing new products. Thus, these companies recognize special relevance to strategies to enhance creativity and capture innovative ideas that can be introduced in products they already sell or developing new products. This recognition and need is aligned with open innovation strategy, recommended by Chesbrough (2007).

The **Ideation** category explains the strategies and ideation process implemented within these companies. This category will come out contributions for planning the projects to be developed by companies, implemented in **Roadmap** category and establishing in each moment what projects should be implemented.

The other concepts that have arisen which are related to the concept of Project are the following: (1) **Process**, embodying the objective of the project by Discovery and Delivery categories. The goal of the project is often established by the resulting contributions of Ideation category; (2) **Client Relationship**, which are established by the project often indirectly once the customer contributes to the evolution of the product through the ideation process, however, they also often have a direct interest in the project both collaborating in its development as in testing and experimentation of the products in real environment; (3) **Intellectual property**, which is one of the results of the project, implemented by product licenses, patents and confidentiality agreements; (4) **Knowledge Management**, used and applied in the development of the project; (5) **Partners**, which refers mainly to companies and external experts that are often used as the project evolves; (6) **External knowledge**, which arises mainly from partners and customers and that is embedded by the project.

In this study we can enhance the concept of Ideation where are represented the strategies implemented by companies to stimulate and promote creativity and innovative ideas. The concept is implemented by four distinct and subsequent stages of the ideation process (idea generation, idea selection, viability analysis and project implementation) and in each phase there can be contribution from external entities, namely customers and partners. However these companies still being too closed to their own boundaries, using platforms and tools to promote creativity and ideas

development, but only with their employees and in the cases they involve customers and partners, they are carefully selected.

We also notice that the external partners are mainly, and almost exclusively, universities and research centers and labs. Companies enhanced that these relationships are worthwhile at any phase of the ideation process, however they often take place in specific projects, mainly when they are researching some really new technology.

It should be noted too that these companies often use their customers to test and evaluate new products and/or new features that aim to market. By this way, they can assess the relevance and interest of the introduction of products on the market to potential customers. However, this is also a practice that has been little explored and when performed customers are also carefully selected.

Aligned with the fundaments presented by Chesbrough (2007) referring the advantages of open up the companies boundaries to external knowledge as a way of speeding up the introduction of innovation in companies product and processes, there is the strategy of crowdsourcing innovation (Bonabeau, 2009; Erickson, Petrick, and Trauth, 2012; Howe, 2008; Majchrzak and Malhotra, 2013). We define crowdsourcing innovation as all crowdsourcing initiatives developed by an organization that strengthen the organization's capacity for innovation. That is, any initiative to create value and/or capture value by taking advantage of existing knowledge outside the organization and accessible from the network of individuals connected to the Internet, regardless of the type or degree of complexity of the necessary development work.

The implementation of this strategy needs more carefully research according to companies and projects characteristics, namely by deciding the way it should be implemented: in a specific project developed by the company, using a crowdsourcing innovation broker, or company developing its own platform for crowdsourcing innovation.

Abstract

Cyber-Physical Systems (CPS) is a combination of computation and networking systems with the physical systems that interact together in complex ways and rising uncertainty. Common examples of CPS include power generation grid, industries, water distribution, health care systems and aviation. Many governments, companies and research institutions nowadays are seeking competitiveness over this technology. Security is one of the key concerns in CPS due to their cyber-physical nature and interaction. To safeguard the CPS resources and tackle the security issues, a well-designed risk assessment approach is essential. The available risk assessment approaches in the area of cyber security may not be applied directly to the CPS since they are different in many aspects.

Keywords: Risk Assessment, Risk management, Cyber Physical Systems, Smart Grid, COSO.

1. Introduction

Cyber-Physical Systems (CPSs) are known as the new generation of mix systems consisting of computational and physical capabilities. A CPS aims to monitor the physical processes behaviours and then take actions to make the physical environment work properly and better(Stoneburner et al., 2002, Wang et al., 2010). The embedded devices in CPS are also networked to sense, manage and monitor all the physical components . The CPS has tight integrations among the computation, networking, and physical objects. It is generally used in critical national infrastructure, for example, electric power, water distribution systems, petroleum systems and so on. Current CPS is facing the issue of a huge security risk since these kinds of systems are becoming interconnected in many ways to the internet in order to increase functionalities and achieve automation (Yong et al., 2013).

This research identifies the effectiveness of the risk assessment approaches in order to secure the Cyber-Physical Systems from the cyber-attacks. The Smart Grid is chosen as a specific domain example of CPS to model problem in this research. A comprehensive list from an extensive literature review of the available known risk assessment approaches or methodologies is presented for the CPS and Smart Grid. Finally, it presents a preliminary risk assessment approach developed in the Smart Grid environment. The proposed risk assessment approach helps achieve a continuous risk analysis in Smart Grid projects by enabling an early start and flexible adoption.

2. Background

The Cyber-Physical System (CPS) is a combination of physical systems with cyber systems. In addition, new capabilities such as real-time perception and dynamic control are added through integrating networked computational resources into physical processes (Lee, 2008). Nowadays, CPSs are being applied in the chemical engineering, electric power, steel industries, and many others critical areas. Security is an area of concern for all the information technology systems which needs to be addressed (Zhang et al., 2013). The growing cyber threat environment is becoming more complex and the ability to

have an appropriate defence is becoming rather difficult (Yong et al., 2013). Thus a well-designed assessment approach for the CPS risks will help in providing an overall assessment of CPS security status and effective allocation of the resources. Risk assessment is one of the main processes in controlling and evaluating risks. It helps in supporting the higher management of the organisation in decisions related to prevention, detection and correction of critical issues and threats (Stoneburner et al., 2002)

There is also a need of a study about integrating the technical and management aspects of evaluating and monitoring the risks within a risk assessment framework. Since the results of such assessment approach have significant influences on decisions of the countermeasures and plans, it is vital that more effective risk-assessment approach should be advanced.

3. Cyber-Physical Systems and Risk Management

The technologies of the Cyber-Physical Systems (CPS) are becoming increasingly important as they guarantee to provide a comfortable, healthy, secure, and safe environment. To improve their functionalities and operations, most critical infrastructures are now being prepared with the modern CPSs(CSRA, 2013). Unlike the traditional computer and network systems, the Cyber-Physical Systems are complex systems of systems where vulnerability and risks can have new and distributed impacts. A critical damage can occur, if the physical environment is taken over by any type of malicious attacks. Using a CPS can provide more opportunities to terrorists which may destroy the critical infrastructures. Therefore, it is required to ensure that a CPS's environment is safe, secure, well-organised, and real-time (Wan et al., 2010). Subsequently, new risk assessment methodologies are needed to be applied in the CPS (CSRA, 2013).

CPS security is an emerging area and generally can be defined as the ability of the systems to allow only authorised access to its data and operational capabilities. The security objectives of CPSs are Confidentiality (Han et al., 2007), Integrity (Madden et al., 2010), Availability (Work et al., 2008) and Authenticity (Wang et al., 2010). The major attacks on CPS are eavesdropping, compromised-key attack, man-in-the-middle attack and denial-of-service attack. The cyber security is a very critical concern that is predicted to be among the fastest growing segments of the Information Technology (IT) sector (Watts, 2003).

Risk management plays a critical role in any organisation. It helps to manage the risks by supporting and safeguarding the organisations' critical assets. An effective risk management process is essential for the successful IT security program. Risk management defines the appropriate risk mitigation approaches to ensure continuous benefits of assets by choosing among different alternatives to minimise the effects of risks (Habash et al., 2013). Therefore, risk management should be treated as a significant management function (Stoneburner et al., 2002) for CPS. For any risk management, it is expected to analyse the worth of assets, the incidents that may affect the assets, the possible threats and vulnerabilities and their likelihood of occurrence. The basic steps for risk management process must be to analyse the triggering event, estimating the loss if the event occurs and estimating the possibility for the event to occur (Djemame et al., 2014).

4. Smart Grid and Risk Assessment

The term *grid* is used to describe the electricity system when it supports the operations of electricity generation, electricity transmission, electricity distribution, and electricity control. The main purpose of designing the power grid was to transport power to the end users while maintaining a centralized power flow and control structure. In order to control the power flow and demand, grids have been introduced from the integration of distributed generations in the power systems. Moreover, the new deployment of the communication network like Supervisory Control and Data Acquisition (SCADA) systems and

Advanced Metering Infrastructure (AMI) has made the control of these complex power systems more stable, reliable, flexible, and efficient(G. N. Ericsson, 2010).

The advanced ideal functionalities of the Smart Grid are self-healing capability, interaction with customer, resistance to attack, betterment in power quality, accommodation of a network of generation, and storage options, enabling electrical markets, optimising assets and efficient operation(G. N. Ericsson, 2010). Smart Grid is also expected to lower the cost and minimise the asset failure. According to(X. Fang, 2012), the Smart Grid is technically divided into three main systems, which are smart infrastructure, smart management, and smart protection systems. The National Institute of Standards and Technology (NIST) have provided a conceptual model for the new Smart Grid which can be used as a reference (X. Fang, 2012)model. The model is divided into seven domains, at the same time, it includes the devices, systems and programs that help in decision making and information exchange which are required for the application to perform.

Smart Grid risk can be defined as the probability of threats that may use the vulnerability to cause harm to a computer, network, and system. The attack will then result in operational and business consequences for the Smart Grid. Thus, the main objective of the Smart Grid's cyber security risk assessment is to identify different vulnerabilities and threat risks and then determine their impact. Ultimately the outcome of the risk assessment should be used to define the security requirements and control(Hecht et al., 2014). For this purpose, the best practice for the Smart Grid risk management process was presented by the National Rural Electric Cooperative Association(Lebanidze, 2011). The guidelines for Smart Grid Security was developed by NIST (NIST-IR 7628) (Group, 2010). However, they do not provide a general approach for assessing cyber security risks. The report on Smart Grid security by European Union Agency for Network and Information Security (ENISA) was based on NIST-IR 7628 and ISO 27002. ENISA provides a set of specific security measures which meant to establish a minimum level of cybersecurity and recommends the risk assessment should be performed during the system life cycle (ENISA, 2012).

The process of the risk management mainly includes assigning priorities to risks and establishing a proper budget to measure and implement such process which is one of the most important high management responsibilities. In this respect, it is critical to follow a risk assessment approach that will provide an assistance to the management at the first stage. Smart Grid cyber security risks can be categorised in three categories: people, process, and technology (Lebanidze, 2011).

5. Security Risk Frameworks and Standards

Technology is being used increasingly in almost all businesses. However, the information security in systems was not incorporated earlier and only recently has attracted attention. The hidden weaknesses which are the systems vulnerabilities, need to be identified and managed accordingly(Al-Ahmad, 2012). Cyber security is an information security and involves the same three core principle of Confidentiality, Integrity and Availability since these cyber threats are results of the weaknesses and vulnerabilities in the system (Lindau, 2012).

The NIST's cyber security framework for the cyber security may not constitute a fool-proof formula that includes leading practices framework. The Framework owns or operates in the organizations' critically targeted infrastructure, while in fact, the adoption proves beneficial for businesses virtually all industries(Al-Ahmad, 2012). The standards in general, are meant to provide uniformity that would ease the understanding and management of the concerned areas. The businesses find themselves in a need to adopt standards for various reasons which vary from business requirements to regulators and compliance mandates.

ISO 27001 (formally ISO / IEC 27001), an Information Security Management System (ISMS) is a specification. An ISMS in an organisation's information risk management process which includes all the

legal, physical and technical controls that include a framework of policies and procedures (Al-Ahmad, 2012)ISO 27001 is about "installation for implementing, operating, monitoring, reviewing, maintaining and improving an Information Security Management System to provide a model"(Almorsy, 2011). ISO 27001 is a top-down, risk-based approach and the technology is neutral. Whereas Information Technology Infrastructure Library (ITIL v3) deals with service strategy and service design by focusing on the definition. Their goal is a new service and the improvement of an existing one. NIST Risk Management Framework (RMF) is an information system for the selection and specification of security controls for organizational risk management. Operationally Critical Threat, Asset, and Vulnerability Assessment (known as OCTAVE) determine the level of risk and planning defences against cyber-attacks by a security framework. In OCTAVE, people within the organization get leveraged, and so, the experience and expertise is built. The first step that they pose is to build threats based on risk profiles. The process to conduct a risk assessment relevant to the organization is a continuous one(Alberts, 1999). The Committee of Sponsoring Organizations of the Tread way Commission (COSO) has published an Internal Control – Integrated framework in 1992. The joint initiative aims to provide guidance on enterprise risk management, internal control and fraud deterrence and this is through the development of frameworks(Spira and Page, 2003).

Risk frameworks require the organizational assets, inventory risks, definition, control, evaluation and risk, ending up with an estimate of a magnitude. Perhaps the most well-known risk framework OCTAVE comes in three sizes based on the organisation magnitude. OCTAVE's latest product in the series is more of a trivial texture and has a more focused approach than its predecessors. One of the benefits of OCTAVE series worksheets is to document every step in the process providing templates for each of the arrangements. These are either directly used or intended to be used for a particular organization. Different types of organisations are continuously exposed to many kinds of risks. The Committee of Sponsoring Organisations of the Tread way Commission (COSO) framework is one of the available frameworks that provide risk assessment process within its risk management processes. The COSO emphasises on the development of a framework that will fully integrate the management of risk into the organisation.

6. Proposed Approach Based on COSO

The traditional ways of dealing with risk have changed from avoidance of risk to management of risk. The newly introduced concept of "sweet spot" is being referred to the best way of dealing with risk (Klamm and Watson, 2009). The organisations, therefore, need to assess risks in the first place before deciding which action is to be taken. Basically, a need has emerged for a risk assessment design to be used by ERM (Enterprise Risk Management). COSO ERM provides such an approach as shown in figure 1. The proposed approach follows five defined stages or steps. These steps allow a risk analyst to understand the system, define relevant threats and then identify system risks along with their levels. The five steps of the proposed approach consider and follow the COSO ERM risk assessment process and they are described along with some guidelines as to how they can be applied in the context of Smart Grid. The risk assessment process includes business process requirements and assets' identification, risk identification, development of assessment criteria, assess risk and prioritising, and presenting risks. These steps are discussed in the upcoming sections.

Fig 1: COSO risk assessment process (Curtis, 2012)

6.1 Business processes requirement and assets' identification

The objective of the first step of this approach is to define the business process requirements of the system and define system assets that require protection from any security threats. The value of any asset depends on the role that it plays in the business process. The stakeholders define the business processes that need to be protected and the process owners define the assets of these processes that require protection(Curtis, 2012). The nature of these assets may vary in the Smart Grid environment but generally includes Information assets, functional assets and system assets.

6.2 Risk identification

The objective is to identify and produce a list of key risks of Smart Grid system. Risks are the outcomes of threats and vulnerabilities in the system. The risk exists if a cyber-attack is successful in a particular system(Curtis, 2012). This step is the key part of any risk assessment process. In this step, risks of different levels of the Smart Grid application or system are identified and listed.

6.3 Assessment criteria development

The goal is to develop an assessment criterion to be used in the assessment process of the defined risks**.** Developing a common set of assessment criteria is another key activity in the risk assessment process and to be deployed throughout the organisation processes(Chen et al., 2014). Any type of risk could be assessed by its impact and likelihood. Some organisations evaluate risk along with the vulnerability. A standard comparison and a common form of measurement are required across the organisation(Curtis, 2012).

6.4 Assess risks

The objective of this step is to conduct the risk assessment on the defined risks. While assessing the risks, values are assigned to them and the opportunity using the criteria which has been defined earlier(Chen et al., 2014). This can be done in two steps or stages: firstly, the risks are assessed by using qualitative techniques and then a quantitative analysis is done for the most important risks. The qualitative assessment of each risk and opportunity is based on the defined descriptive scales which are described previously.

6.5 Priorities and present risks

The final step is prioritising the risks and reporting them to the management which is done after viewing and reviewing a comprehensive portfolio. A risk profile presents the complete organisational risk portfolio. The prioritisation process is about determining the risk management priorities and it is done by comparing risk level against predetermined business targets (Curtis, 2012). This process of prioritisation will present a simple and consolidated list of defined risks in an understandable format. This process will help in sorting the risks into their priority order and basically the highest risk level to start with. The risk portfolio can be presented in different ways such as a hierarchy, risk maps, and heat maps. The flowchart of the developed approach is shown in figure 2.

Fig 2: Proposed risk assessment process for smart grid

7. Analysis and Discussion

This section focuses on analysis and discussion of the main variables in terms of the structure of the proposed approach and the other two approaches which have been discussed as the Smart Grid risk assessment examples in the previous sections. For the purpose of this study two approaches were selected and highlighted in order to provide a clear picture of the available approaches in this area. These approaches are RAPSA (Risk Analysis and Probabilistic Survivability Analysis) and Multi-elements and Multi-Dimensions risk evaluation. Both approaches are used in the Smart Grid environment and the strategy which is used in these approaches to understanding the threats to the system is from the ground level. RAPSA has been heavily discussed, adopted and implemented across several studies (Taylor et al., 2003, McGuire, 2014, Morris, 2015, Swiderski and Snyder, 2004, Taylor et al., 2002). At the same time, critical assets will be identified as they are the most vulnerable components in the power grid (Taylor et al., 2002).

7.1 Analysis of risk assessment approaches

As it has been pointed out earlier that a very few risk assessment approaches and methods are available for the CPS. There is a non-availability of proper method and approach that takes care of the whole assessment process. Most of the guidelines in the area of Smart Grid risk assessment, such as NIST, show several important steps and best practices that must be available in any risk assessment in this area. The best practices for the risk assessment approaches include asset identification, risk, threats & vulnerability identification and assessment of risks & determine priorities. Based on the best practices, Table 1 illustrates the analysis and comparison of the approaches.

Table 1: Assessing the risk assessment approaches

Approaches **Assessment process(best practices)**	**RAPSA**	**Multi-elements and multi-dimensions**	**The Proposed Approach**
Management/ Business objectives			√
Asset identification	√	√	√
Define Assessment criteria		√	√
Risk, Threats and Vulnerability Identification	√	√	√
Assess Risks	√	√	√
Determine Priorities			√

7.1.1 Asset identification

Identifying the potential assets is an essential first stage in the risk assessment process in order to develop proper responses. The RAPSA risk assessment approach (Risk Analysis and Probabilistic Survivability Assessment) is used in case of cyber-attacks at the power station. There are four main steps to perform risk assessment: System's self-assessment, threat identification, risk quantification, and risk mitigation trade-off. The system's self–assessment assures that the team understands the overall objectives and partition the system into basic services. However, there is no clear identification of the system's critical asset that needs to be protected against the cyber-attacks and which has a more business value. The multi-elements and multi-dimensions risk evaluation methods assume that the area is defined and start the process with the risk identification based on the defined risk factors in order to do analysis based on risk sources. In this approach, the process of risk assessment misses the asset identification step, and there is no clear direction for which type of assets the assessment should be done. The proposed approach in this research starts with very a basic information which is required in any risk assessment process. The first

and entailed step of asset identification and stockholder requirements defines all the critical and important assets that need to be protected along with that link with the business objectives of the organisation.

7.1.2 Risk, threats and vulnerability identification

Planning is an important aspect in the risk assessment process, and securing a Smart Grid environment fully addresses the risks and vulnerabilities(Boyer, 2009). The risk identification and classification is performed to develop appropriate security measures. This process of identification involves the assessment of critical components and weak areas in security and it is frequently implemented to monitor the compliance status of the system. The RAPSA's second step of risk assessment is the threat identification, and cyber-attack threats are estimated from the defined essential services, and then identifying the vulnerabilities. However, the method does not clearly mention how these threats and vulnerabilities can be measured or quantified. These factors can be a likelihood or probability to damage any asset of the organisation and can be quantified by threat matrix or frequency. On the other hand, the multi-elements and multi-dimensions risk evaluation approach starts with that step of risk identification and classification. The identification as mentioned is based on specific factors like policy, market and management. The proposed assessment approach has defined a clear step of risk identification which comes from different threats and vulnerabilities. It is the key part of this assessment process and produces a comprehensive list of risks that are organised by risk categories and sub categories. The risk identification can be done by considering all possible risks that are defined by the process owner or by using one of the defined techniques to identify risks as mentioned.

7.1.3 Assess risks and determine priorities

In the risk assessment process, determining and defining assessment criteria is one of the important steps in order to assess the risks. The assessing of risks enables an appropriate and proportionate targeting of security recourses and controls. The risk identification phase is followed by the assessment and prioritisation of the risks. Before being able to determine the risk's likelihood or the risk's impact, the assessment criteria needs to be formulated for each factor. In the RAPSA method, the assessment criteria are missing. The analysis of the risks comes in place with quantifying the risks for each intrusion scenario and then it uses the event/fault trees. The event/ fault trees are simple techniques which are used for modelling risks and underlying the relationships. In this stage of quantifying the risk for each intrusion or attack scenario, the historical data is used or expert opinion is asked when this data is missing to estimate the damage. This means that there are no defined criteria for the assessment. On the other hand, the multi-elements and multi-dimensions risk evaluation approach adopts a risk evaluation matrix that uses the time and regional development in consideration with the general process of risk management. The assessment process in this approach is based on the risk factors and risk probabilities clarifications. Then a formula is used to define the risk level and format of risk matrix. The values are classified based on the defined range of standards to present the size of the risk. In this approach the clear assessment criteria are used to define the risk level and that is used to define the controls for each risk.

For the proposed approach in this research, the assessment criteria are developed for each risk event and presented by scales. In order to assess the risk, an organisation is required first to define the scales for each impact, likelihood and vulnerabilities which are used in the risk matrix to calculate the values. The assessment is carried out and values are assigned to each risk by using the criteria which are defined earlier. Next, the risks are assessed by using qualitative techniques and then if required quantitative analysis is done for the most important risks. In this approach clear scales are used to evaluate the risk.

8. Conclusion

With the increasing need for the proper security of the CPS infrastructure from cyber-attacks, a large and diverse number of risk assessment methodologies have risen to help to achieve this goal. Proper guidelines and standards are needed to be used to develop an appropriate risk assessment for the CPS and

fulfil the security requirements for such critical systems. In this research, an extensive literature review was done in the area of the CPS risk assessment in order to provide the basic information regarding the available studies and efforts in this area. Furthermore, a list of the most relevant frameworks and risk assessment approaches for the CPS and mainly for Smart Grid has been analysed.This research is an important step towards the goal of having a well-designed approach for evaluating and controlling the cyber security risks in the area of CPS and Smart Grids. Future research may include further work and research to draw a complete conclusion about the implementation and testing of this approach in order to validate the results. Also, the proposed approach can be studied to fulfil the requirements of other areas of the CPSs. The proposed approach must as well be subjected to further verification to increase the quality of the assessment results.

Acknowledgment

The research leading to these results has received Project Funding from The Research Council of the Sultanate of Oman under Research Agreement No. [ORG/SQU/ICT/13/011]. The authors would like to thank TRC,CBO and SQU for all the administrative and financial support.

Abstract

The scientific paper presents the results of the economic analysis of the needs of basic food types for the inhabitants of the Czech Republic. The performed analysis is based on the calculation of the fulfilment of energy intake per person per day. The population was divided by sex and age to determine the energy value of food intake through the use of basic food types. The observed data can serve as a basis to determine the level of food self-sufficiency in our country and as a basis for assessing the food security of the Czech Republic.

Keywords: Food self-sufficiency, food security, energy intake, basic food types

Introduction

The paper is an analysis of basic food types needed for inhabitants of the Czech Republic since the age of three; the population is divided by gender and age with respect to the energy needs of the various population groups. Based on those assumptions and economic study there is then across the energy value calculated on the basis of basic food types needed for inhabitants of the Czech Republic by region. This information could serve as a basis for food self-sufficiency, which is part of food security. Simultaneously, this data may also serve bodies of the state and local governments in preparing for emergencies in the context of economic measures for crisis situations (e.g. studies about population protection against floods, Šafařík et al., 2015).

Research and Findings

In the research have there been adopted following assumptions in order to determine the necessity of food for each region of the Czech Republic:

- Energy value is always determined as an average caloric intake for each age group with respect to gender, age and average weight with regard to physical activity. It is therefore determined the baseline measurement of calories required for basic conversion (basal metabolic rate) plus PAL (physical activity level) = average daily energy requirement for physical activity as a multiple of basic metabolism.

- Body weight is calculated from measured heights and under optimal BMI value of 22 for men (age range 15-18 years) and value of 21 for women (age range 15-18 years); value of 24 for men (ages: 19-24, 25-29, 30-34, 35-39, 40-44, 45-49, 50-54, 55-59 and 60-64 and 65+) and value of 22 for women (ages 19-24, 25-29, 30-34, 35-39, 40-44, 45-49, 50-54, 55-59 and 60-64 and 65+).
- For men of all ages from 15 to 64 years of age including, PAL is set at a value of 1.8 (activity mostly standing and walking) for ages 65+, PAL is then at 1.2. For women of all ages from 15 years to 64 years of age including, PAL is set at a value of 1.6 (sedentary activity with occasional light activities while standing or walking) for ages 65+ PAL then at 1.2 (same for men and women)
- Children are divided by gender and age into several groups; the youngest age group is 3 years old. Children from 0-3 years of age are not included in the study. Energy value is again determined according to dietary reference values.
- All data relating to population, gender and age are the official data by the Census of people, houses and flats from 2011 - the CSO statistics.
- Population is divided into groups according to tender and age.
- Figures will be given in kJ and Kcal (for better comprehensibility).
- A healthy individual is always considered who can receive traditional diet without restrictions.
- There are not taken into account the different dietary habits based on religious, ethnic or other reasons, the individual does not consume certain types of food or he consumes them only after a specific type of treatment.
- The types of food that are used to meet the energy needs of different population groups have been established under prescribed necessities for survival of an inhabitant for 10 days (Foldyna, 2009).

To illustrate the situation in Table 1 the data is provided on the required energy and its coverage of essential food types in men with regard to their age, physical activity and weight.

Table 1: Expressing the necessary energy value of the basic types of food for men

Age	**Men**				
	Body weight in kg	Energy value in kJ/day while counting PAL	Food type	Food amount in grams	Energy value of food in J
15 – 24	67	13707 (13707)	Meat and meat products	90	870
			Milk and dairy products	240	1128
			Lipids	70	2037

The following graphs and maps show the value of total supplies of basic foodstuffs for the day and year for men, women and children, summed always based on individual calculations for each group into groups of men 15+, women 15+, boys 3-14 years old, girls 3 - 14 years old and children 3-14 years old in total, with total population of the Czech Republic from 3 years of age. The following Table 2 shows the population of the Czech Republic, according to the last census in 2011.

Table 2: Population of the Czech Republic according to the Census of people in 2011

	Boys 0 – 14 years old	**Girls 0 – 14 years old**	**Men 15+**	**Women 15+**
Population	763 949	724 979	4 325 915	4 586 090
Total	1 448 928		8 912 005	

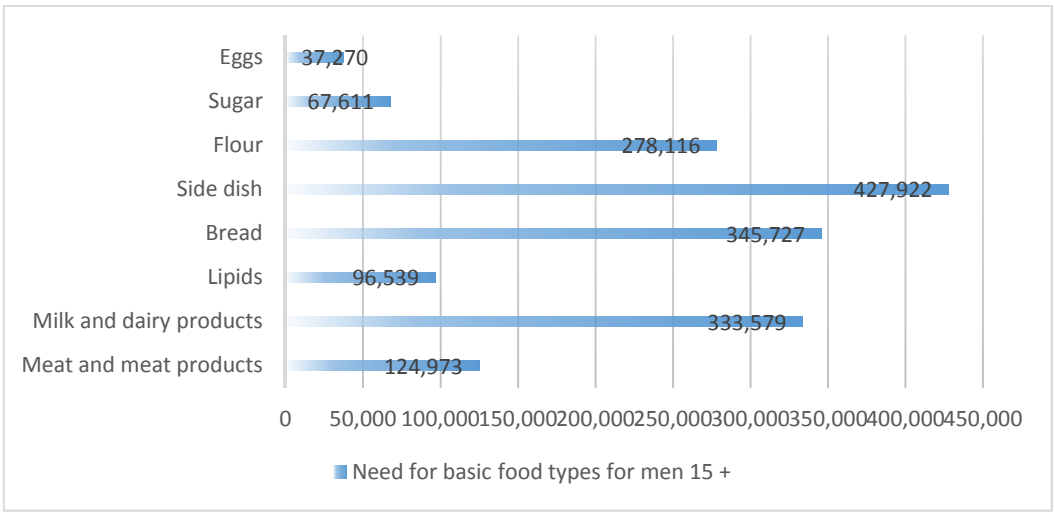

Fig. 1 :Need for basic food types for men 15+ in the Czech Republic for one year (in tonnes)

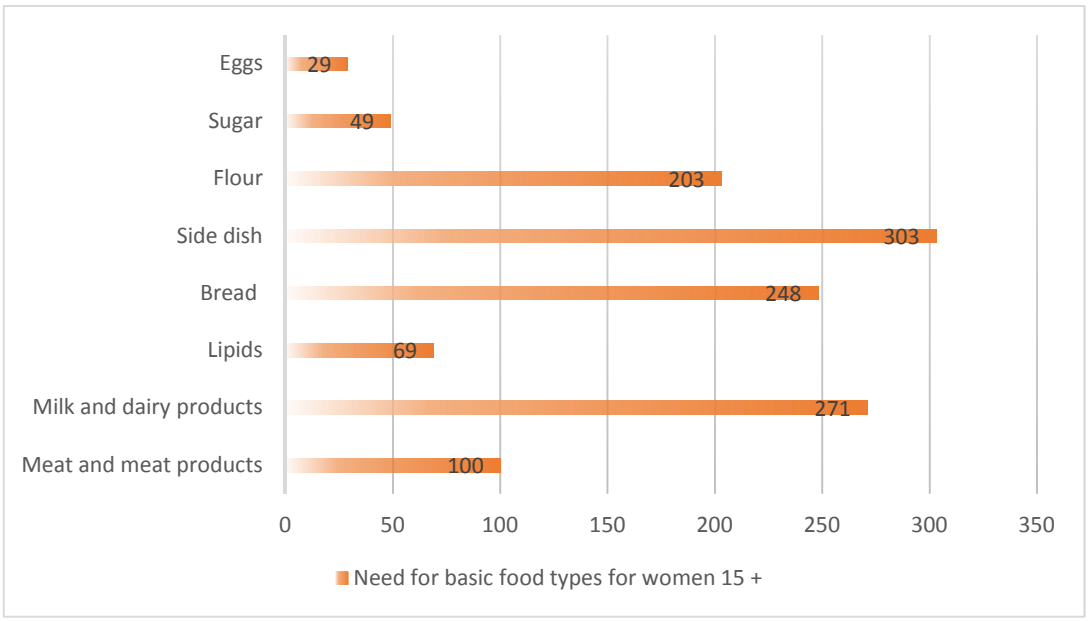

Fig. 2: Need for basic food types for women 15+ in the Czech Republic for one year (in tonnes)

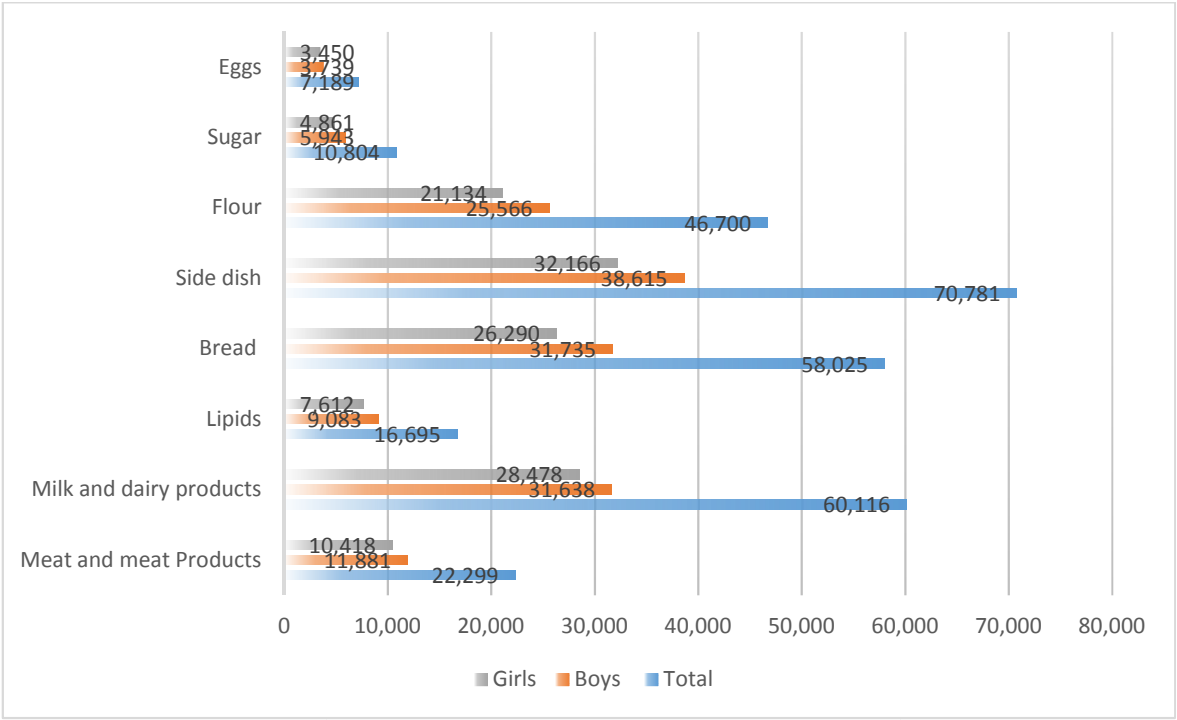

Fig. 3 : Need for basic food types for children 3 - 14 in the Czech Republic for one year (in tonnes)

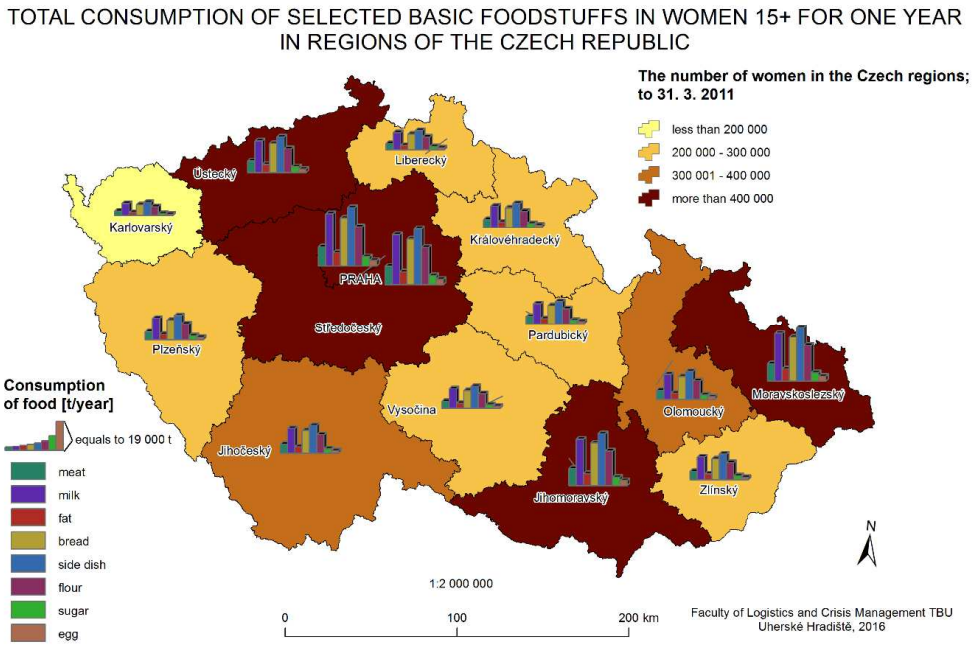

Fig. 4: Total Consumption of Selected Basic Foodstuffs in Women 15+ for one Year in Regions of the Czech Republic

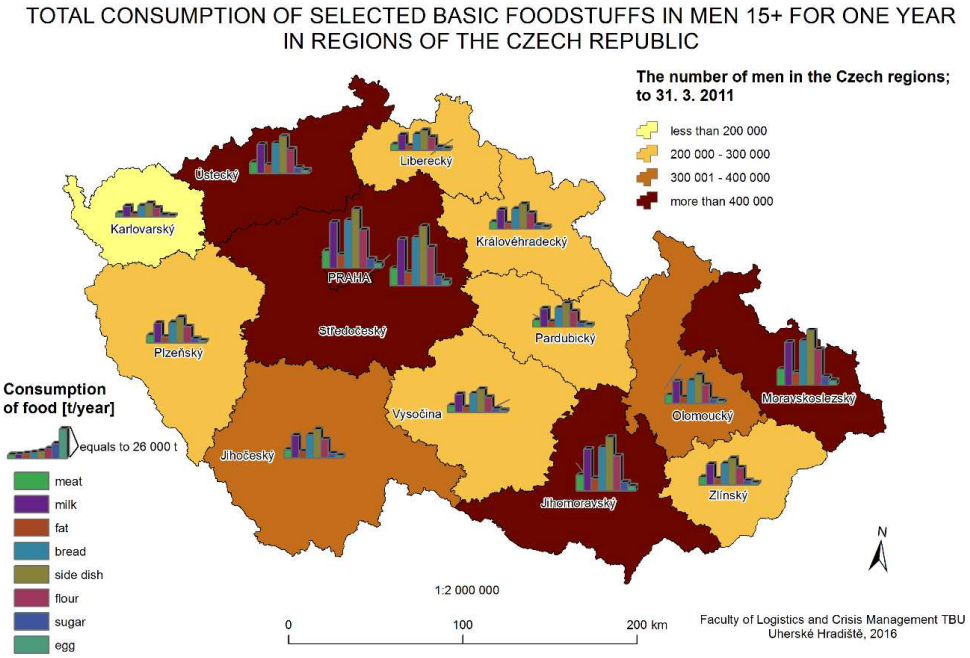

Fig. 5: Total Consumption of Selected Basic Foodstuffs in Men 15+ for one Year in Regions of the Czech Republic

Conclusion

There are following results derived from the analysis of the needs of a number of basic food types for the inhabitants in the Czech Republic on the basis of the specified energy value of food intake: energy needed for different population groups was met by eight basic food types. For different population groups, which were divided by gender and age, it was determined necessary amount of meat and meat products, milk and dairy products, lipids, bread, different types of side dish (potatoes, rice, pasta), flour, sugar and eggs. The results can be used to determine the value of food self-sufficiency in food types evaluated for the Czech Republic. In the paper there were presented some of the results of the economic study.

Abstract

Sustainable competitive advantage is important when companies keep searching new ways to offer value better than their competitors, especially when the competitive environment changes. Knowing which elements of competitive advantage to deploy would help companies set effective competitive strategies from the very beginning. Intellectual capital as intangible resources is important for a sustainable competitive advantage. The main concerns of this paper are to identify the elements of sustainable competitive advantage of small and medium enterprises and how intellectual capital influences sustainable competitive advantage. Focus group approach was used to explore the perception of sustainable competitive advantage and intellectual capital of SMEs. Content analysis was analysed using a mechanical method. The findings show that cost leadership and differentiation strategies are commonly used by SMEs to achieve sustainable competitive advantage. In addition, innovation is considered vital to create value for customers. The majority of the participants agreed that human capital is the most important element of intellectual capital regardless of industry. Innovation capital is regarded more important than relational capital and structural capital.

Keywords: Sustainable Competitive Advantage, Intellectual Capital, Small and Medium Enterprises

Introduction

In a turbulent and competitive environment, having competitive advantage will help a company stay profitable and ahead of its competitors. However, competitive advantage alone does not guarantee the company will remain relevant. Companies should strive for sustainable competitive advantage to remain in the business for the long term. This can be achieved by leveraging and capitalising their internal resources and capabilities. Intellectual capital is a key driver of innovation and competitive advantage in a knowledge based economy (Taie, 2014; Guthrie and Petty, 2000) where learning and knowledge are the key parameters of sustainable competitive advantage (Hana, 2013). Most studies on competitive advantage and intellectual capital employ the quantitative approach gather general ideas or perception of large population which means that the real and hidden answers were not recorded. Furthermore, SMEs have limitations compared to large organisations such as limited resources, lack of experts, and lack of impact especially in strategic approaches, role of owner/manager and lack of formalised policies and practices (Darcy et al., 2014). A qualitative study would help explore in depth of sustainable competitive advantage, intellectual capital, and innovative intelligence among entrepreneurs. This paper investigates the sustainable competitive advantage of SMEs and the link of intellectual capital and innovative intelligence of SMEs in Malaysia through the use of focus group.

Sustainable Competitive Advantage

Competition has forced SMEs to set their competitive advantage (Kocoglu et al., 2009; Hana, 2013). They have to identify new ways to satisfy their customers and provide value better than their competitors. When customer value firms offer more than that of their competitors, they attain competitive advantage (Choplin, 2002; Ipek, 2009; Ismail, 2014). Kotler (2000) defined competitive advantage (CA) as the capability of the organisation to carry out its activities in ways other cannot imitate. By having its CA, the firm builds its base for a strategy (Daou et al., 2013). A firm that differs from its competitors and remains outstanding to their consumers would gain sustainable CA (Darcy et al., 2014; Gonzalez-Loureiro and Dorrego, 2012; Khan, 2014). CA lies in the resources and capabilities that produce products or services (Papula and Volna, 2013).

Sources of CA depend on the internal resources or assets of the organisation either tangible or intangible. Tangible assets comprise financial, physical, and technological assets while intangible assets are human, innovation, creativity, and reputation (Papula and Volna, 2013). They emphasised that the source of CA is an intangible asset comprising human capital, structural capital, relational capital, and customer capital. In contrast, according to Alawneh et al. (2009), SMEs have unique characteristics that prevent them from developing a CA compared to large organisation. Nevertheless, Papula and Volna (2013) highlighted that SMEs can more easily differentiate from their competitors because they are fast to adapt to the changing environment compared to larger organisations.

Based on resource based theory, CA can be achieved if the organization's resources are valuable, rare, hard to imitate, and non-substitutable (Barney, 1991). Porter (1980) established three generic strategies which are cost leadership, differentiation, and focus. Cost leadership strategy focuses on cost reduction by selling cheaper than competitors. Differentiation strategy is where companies differentiate their products by features, product mix, services and product complexity. Focus strategy concentrates on a market niche where the company tries to maintain its market leadership. A company can achieve its CA either by operating at a low cost, or by charging a premium price, or by doing both (Porter and Stern, 2001). A survey in Europe found that differentiation strategy is more attractive and suitable to small companies as they are more innovative (3i European Enterprise Centre, 1994).

Barney (1991) emphasised that a firm possesses sustained CA when it adopts a strategy that is, "not simultaneously being implemented by any current or potential competitors and when these other firms are unable to duplicate the benefits of this strategy." According to Coyne (1986), sustainable competitive advantage is when the company is able to maintain the durability of its attractive attribute gap for a certain period of time. As long as competitors cannot fill the gap, the company has a sustainable competitive advantage.

Intellectual Capital

Intellectual capital (IC) has gained popularity, especially in the knowledge based economy. IC studies have focused on large organisations. Studies of IC have extended to SMEs to help them perform better. Generally, IC is knowledge, information, skill, experience, intellectual property that can be put to use to create wealth (Stewart, 1997). Bontis (1998) further elaborated that IC is about the pursuit of the effective use of knowledge (the finished product) as opposed to information (the raw material). Cohen and Kaimenakis (2007) concluded that IC comprises valuable intangible resources containing knowledge that can be used by the firm to accomplish its goals. However, these intangible resources must be complimented with effective management to provide the firm with sustainable competitive advantage. Basically, IC can be located in its people (human capital), its structures (structural capital) and its relationship with stakeholders (relational capital) (Bontis, 1998; Marr, 2008; Ling, 2012;

Human capital (HC) comprises employees' skills, commitment, competence, attitude, capabilities, talents, creativity, and knowledge as an organisation's intangible assets that can be turned into CA (Cohen and Kaimenakis, 2007; Chen et al., 2004). HC can be described as, "knowledge, skills and experience employees take with them when they leave the company' (Djurica et al., 2014).

According to Mouritsen et al. (2002), HC contains creativity, innovativeness, initiative, adaptability, flexibility, motivation, persistence, expertise, skills, experience, devotion to organisation, teamwork training, flexibility, loyalty, ability to establish and develop relations with other employees in the company and its partners, readiness to accept changes, and ability to learn.

IC by itself is of little value without the leveraging effect of the firm's supporting structural capital resource. The structural capital (SC) comprises systems, structure, corporate culture, the organisational process efficiency, databases, information and production technology (Cohen and Kaimenakis, 2007). SC is the embodiment, empowerment, and supportive infrastructure of HC (Bontis, 1998). SC provides a platform for people to be creative (Stewart, 2000). It is owned by the firm. The management's dedication and efficiency is important for the firm's sustainable competitive advantage (van Zyl, 2005). SC comprises innovation capital, organisational capital, and process capital.

Relational capital (RC) embraces all the relations the firm has established with its stakeholder groups such as customers, suppliers, the community, and the government (Bontis, 1998; Allee, 2000). Specifically, RC fosters a knowledge-producing behaviour – providing a source of ideas for change and improvement by market information processing and marketing strategies (Keskin, 2006). However, this knowledge has little benefit if not appreciated and implemented to enhance firm innovation. According to Martin-de-Castro et al. (2004), IC, especially RC is very much into social networking where the relationship with external parties such as customers, suppliers, and the government play a crucial role in the organisation. However, Mc Elroy (2003) commented that IC itself does not emphasise the value of the relationships between people in firms and between firms and other firms.

More capital has been introduced to help companies achieve better performance and acquire sustainable competitive advantage. Innovation capital (Chang and Hsieh, 2011) and technological capital (Pedro et al., 2010) have helped companies capitalise their knowledge and turn it into innovation and intellectual property.

Sustainable Competitive Advantage and Intellectual Capital

IC components especially HC play a crucial role in establishing and maintenance of CA of a company (Djurica et al., 2014). Knowledge that resides in HC, SC, and RC is a source of a company's competencies and are thus vital in building sustainable CA (Lopez et al., 2006). The interactions of IC elements can result in sustained competitive advantage (Gannon et al., 2009). Researches have highlighted that IC is the basis for the generation of sustainable competitive advantages, and this relationship has been broadly studied in the case of medium and large-sized organisations (Ugalde-Blinda et al., 2014; Gannon et al., 2009; Daou et al., 2013; Akhtar et al., 2015).

Methodology

This is a qualitative and exploratory study. Focus group can be defined as, "a small group of people selected to discuss on a particular topic which is led by a facilitator" (Reinard, 1999 as cited by Kratt, 2003). According to Stokes (2000), focus groups provide the possibility of a shift in the power balance from the researcher to entrepreneurs. Furthermore, focus groups allow participants to focus on the researcher's emphasis (Threlfall, 1999). The focus session provides useful information on participants' perception, experience, and knowledge in their own terms and language (Stewart and Shamdasani, 1990). This paper intends to capture this primary information.

The participants for this study were selected through nonrandom methods. Purposive sampling and networking were used to identify the target group and invite volunteers to participate (Latham, 2007). Personal contact was used to identify the target group and the participants. Participants were informed of the date and venue of the session. Eleven entrepreneurs agreed to attend the session which is within the conventional group size of six to 12 (Millward, 2012; Cameron, 2005).

Two prime considerations for participants are convenience and comfort. We reserved a small business room that can accommodate 15 people. The participants were seated at a big round table so that they would be able to hear and listen to others clearly. Since all the participants are entrepreneurs, they were willing to participate in a two hour session. The success of the session will depend on preparation and good people skills (Greenbaum, 2000; Wilkinson, 2003 as cited by Millward, 2012). Three facilitators and two research assistants were deployed for this purpose.

Prior to the focus group session, a list of questions was prepared. The questions included: what is the sustainable competitive advantage to your firm, what elements of CA are for the firm, which of the elements are important for sustainable competitive advantage for your company and which of the IC elements is the most important for SMEs? During the session, an audio recorder was used to tape the discussion. The entire discussion was recorded directly on tape.

There is no single way to analyse the focus group data (Wilkinson, 2003). The form of analysis will depend fundamentally on whether it is the "content" or the "interaction process" that is the "data" of interest (Millward, 2012). The discussion of content analysis is used to analyse transcription data which can be done either through mechanical or an interpretative component (Krippendorf, 1980 as cited by Millward, 2012). For this study, a mechanical aspect involving physically organising and subdividing the data into categories is adopted.

Research Design

The participants for this study were selected using nonprobability sampling method. Nonprobability sampling is subjective whereby not all members of a population have an equal chance of being selected (Cooper and Schindler, 2003; Reinard, 1999 as cited by Kratt, 2003). The participants were selected on the basis of their accessibility or by the purposive personal judgement of the researcher. For this study, nonrandom tactics used included purposive sampling and networking. The researcher contacted an entrepreneur who is a member of few entrepreneurial associations. The researcher then requested her to extend the invitation to other entrepreneurs who met the requirements of this session. Eleven entrepreneurs agreed to participate in the focus group session.

Results of the Study

The results from the focus group discussion protocol are presented. It is organised under the sustainable competitive advantage, IC, and general reflections.

Sustainable Competitive Advantage

Sustainable competitive advantage (SCA) is important for SMEs to remain relevant in the industry. Depending on the industry, the focus on the elements of SCA would differ as stated by one participant that, *"between cost leadership and product differentiation, it depends on what stage the company is which is life-cycle…"*. Furthermore, the stages and level of maturity of SMEs are other factors that influence the focus of SCA. For example, in the service industry, cost leadership is more important than product differentiation as stated by one of the participants, *"For the service industry, I think cost leadership is more important because it is reflected in our financial budget…"* Another view of one of the entrepreneurs, "*I think depending on the industry, for example for manufacturer they have to focus on product to create CA, however, in service industry basically very competitive. You can imitate your competitor, your competitor could be your benchmark but at the end of the day, you must set your own CA."*

Most participants agreed that cost leadership and product differentiation strategies are equally important and have to be included in the company's CA strategy. However, depending on cost leadership and product differentiation strategies is not sufficient to sustain and maintain their position in the industry. In this study, innovation has been proposed as an element of SCA. In order to sustain the CA, *"…innovation is what we must do to sustain"*. *"I think when we are talking about SCA, we have to focus on innovation which means you to be innovative every day, every month together with*

your employees and so the company's CA can be sustained in the market". The company has to be innovative in creating value for customers and being different than its competitors, *"SCA for us is create value and do differently"*. As innovation is important in SCA, innovation performance should be included as an organisational performance measure. *"Cost-leadership is important to my company. Product differentiation is also what we must have, we should do what our competitors are not doing and do better than them where product and process innovation are important today"*. However, one of the entrepreneurs disagreed, as for her company product differentiation strategy and innovation performance are more important than cost leadership strategy.

Intellectual Capital

In a knowledge based economy, knowledge, which is an intangible resource, is more important than tangible resources like labour and capital. IC comprises HC, SC, and RC has evolved to help the organisation to perform and better acquire SCA. As IC goes in-depth, capitals like technological capital, innovation capital, and spiritual capital have been included. The participants agreed that all IC elements are important for achieving SCA. They are not familiar with the terms and did not realise the importance to identifying and capitalising on IC as stated by one of the entrepreneurs, "*I am glad that today I learned what IC is about. We don't have a proper plan but we have a goal. What we do we just set out our goals and do whatever necessary to achieve it"*. After the explanation of IC, the entrepreneurs were given questions on IC. Some thought that spiritual capital should be included, *"…spiritual capital is important in my company. Spiritual capital is about honesty among staff. Therefore, in order for them to be honest, it is good to have spiritual capital"*. However, another participant disagreed with including spiritual capital, *"I think spiritual capital can become very religious meaning I don't need money… I don't need anything"*.

Participants had mixed views on the importance of IC. One participant stated, *"For my training company, HC is a main priority, follows by RC, innovation capital, SC and technological capital"*. For another training company, *"For me HC is very important, then SC, RC, innovation capital and technological capital"*. SC is whatever is left behind after office hour which includes a database, system etc. *"…some of the structural elements are costly; there are many ways to cut costs. We know many ways to cut costs, for example, we fully utilised google.doc. Whatever transpired between customers and employees, all information will be shared among the employees through cloud application such as google.doc.…". We share information on google.doc between our staff and customers.*

Overall, all the participants agreed that HC is the most important element of IC as stated by a participant, *"even if you have the best SC but not HC, everything will be collapsed"*. For entrepreneurs from the IT industry, *"…in my industry, innovation can be easily duplicated. I have to innovate quickly ahead of my competitors. I have to understand my customers' needs and provide innovative solutions. Therefore, I would say HC is our main priority while innovation capital is next important element. The rest are equally important"*. For another entrepreneur, *"in SMEs we have to invest either in human or relationship. For me, RC is more important than HC"*.

Conclusions

Most entrepreneurs are unaware of how they achieve their CA. They have their own strategies which were rather general and on an ad-hoc basis. It is interesting to discover that entrepreneurs prefer to adapt strategies for cost leadership and product differentiation. The entrepreneurs agreed that in order for SMEs to acquire SCA, they must adopt cost leadership, product differentiation, and innovation performance. However, depending on industry and its life-cycle, SMEs did not necessarily adopt all three dimensions of the proposed SCA but select the one that gives them most advantage.

SMEs understand the importance of IC to achieve SCA. HC is considered the most important elements of IC. Although all capitals are considered important, innovation capital ranks second after HC. Interestingly, entrepreneurs did not rank SC as high as RC which is in contrast to Bontis et al. (2002) and Chen (2004). A qualitative research design proved fruitful in obtaining a description of

practices from entrepreneurs (Stokes, 2000). The focus group session helped the researcher acquire in-depth information which would not be obtained through a quantitative approach. Even though primary information was attained from the entrepreneurs, the findings are not generalisable (Threlfall, 1999). Innovation is important to businesses as highlighted by the entrepreneurs, especially in a creative and knowledge based economy.

This study showed that most of the entrepreneurs set their strategies based on their intuition without knowing the importance of CA. Their main target is to create value so that they are ahead of their competitors. It is important for entrepreneurs to develop their strategies to capitalise on their IC effectively. In addition, the term "IC" seems new to entrepreneurs. It would be beneficial if entrepreneurs knew the benefits of IC and how it would affect and influence their CA. This study was carried out on a small number of entrepreneurs from different industries and with different background. It would be interesting to select participants from a single industry to gathering information on their SCA and IC.

Abstract

Social media has been used to communicate with people worldwide, but recently, with the advancement in technology, it has become a way of reflecting personal life online. It provides incredible tools to create personal accounts that can be easily viewed by others. This may expose people to inappropriate interference and judgment from others and, indeed, have a profound impact on their feelings and on how they evaluate themselves, but this is not the only perspective with which things can be viewed. Social media is a source of inspiration. People are gathering to share their thoughts, interests and achievements. Indeed, the manner in which social media is used differs from person to person, and can range from active to passive use, the effects of its use on individuals being positive or negative.

The objective of this research is two-fold: 1) to investigate the different categories of social media user, and 2) to explore how social media affects their self-esteem. To achieve the research objectives a multi-methods approach was employed: 1) an intensive systematic literature review was carried out, and 2) a questionnaire was distributed amongst different social media users to elicit their opinions on how the use of social media has impacted their self-esteem.

The results reveal that there are seven categories of social media users, which are: creators, conversationalists, critics, collectors, joiners, spectators and inactive users. The self-esteem of all categories of social media user was high. For this reason it can be said that the use of social media has a positive effect on self-esteem.

Keywords: social media, self-esteem, social technographical ladder

Introduction

The interactive version of the web is called Web 2.0. This is an enhanced version of the Internet that enables dynamic user-interaction and user-ability to create and publish web content without special programming. Because of these interactive capabilities of Web 2.0, tools such as Facebook, Google+, YouTube, Twitter, MySpace, LinkedIn, Wikis, podcasts, and blogs have become very popular and are becoming everyday language. Such applications are termed ‘social networks’ or ‘social media’. This phenomenon has become a major part of our lives and many people try to share their day-to-day activities on social networks, and sharing photos and videos is also popular. The rapid rise of social networks has changed the way we interact online, how we connect to people, and, of course, how we market ourselves, our products, and our services. With these tools people have a chance to share and upload information immediately, making data dissemination far more convenient and viral in nature.

Nowadays people are connected with each other more than before through social media. For huge segments of the world’s population, mobile phones, the internet and email, instant messaging, and various forms of digital social media have become deeply integrated into the fabric of daily life [Warf, 2013]. Millions of people are using social media on a regular basis around the world, so that the number of social media users changes literally by the hour [Pérez-Latrel and Tsourvakas, 2013; Westerholm, 2013].

Social media has become a way of expressing and reflecting personal life online. It provides incredible tools to create personal accounts that can be easily viewed by others. This may lead them

to be exposed to inappropriate interference and judgment from others. Undoubtedly this may have a serious impact on their feelings and on how they evaluate themselves. This is not the only side of the coin. Social media is a source of inspiration. People are gathering to share their thoughts, interest and achievements. Indeed, the use of social media differs from one person to another. It could range from active use to passive use of it. Therefore, its effect could be positive or negative on their selves. Therefore, using social media can influence the behavior of users positively or negatively

The objective of this research is two-fold: 1) to investigate the different categories of social media user, and 2) to explore how social media affects their self-esteem. To achieve the research objectives a multi-methods approach was employed: 1) an intensive systematic literature review was carried out, and 2) a questionnaire was distributed amongst different social media users to elicit their opinions on how the use of social media has impacted their self-esteem.

The paper is structured in the following way: Section 2 provides a literature; Section 3 describes the research methodology; Section 4 presents the research findings and discusses them; Section 5 provides a conclusion and suggestions for future work.

Literature Review

Social media

In many cases the definitions of 'social networks', 'social networking', 'social media' and 'social networking sites' overlap. In this section we differentiate between these different terms. First, 'social networks' are traditionally defined as groups of people who, for example, share interests and/or activities. Social networking is the act of participating or interacting with one another within these social networks, and social networking sites are the websites where the interaction happens [Cohen, 2011; DigitalLikeness, 2008]. Many websites could be classified as being "social networking sites". Examples of the most popular and well-known are Facebook, Twitter, Blogger, MySpace, Digg, Google+, Stumbleupon, LinkedIn, Second life, YouTube, and Flickr. Social networking sites deliver content through communication, collaboration/authority-building, multimedia, reviews and opinions, micro-blogging, publishing, photo sharing, entertainment and brand monitoring [Bard, 2010]. They provide to users techniques and technologies such as aggregators, audio, video, live-casting, RSS, mobile, crowd sourcing, virtual worlds, gaming, search, conversation apps and Wikis. boyd [2007] gives another definition of social networking sites as: 'web-based services that allow individuals (1) to construct a public or semi-public profile within a bounded system, (2) to articulate a list of other users with whom they share a connection, and (3) to view and traverse their list of connections and those made by others within the system'.

Social media are defined as network structures where people are connected together. Any activity they do in the network, for example: follow, forward, like, link, rate, review, reply, comment, and send, is consider a network edge [Smith, 2014].

On the other hand, Kaplan and Haenlein [2010] define 'social media' as 'a group of Internet-based applications that build on the ideological and technological foundations of Web 2.0 and that allow the creation and exchange of user-generated content'. Therefore, social media are just like other media, a means of communicating and exchanging information. Social media offer the opportunity to create or disseminate facts, opinions, arguments etc. in many forms (video, audio, image, text), i.e. social media are the platform and provide the tools for self-expression in various forms. Groups of people with common interests are associated together on social media [SocialMediaToday, 2010]. Clearly the term 'social networking sites' and 'social media' are used interchangeably.

The social technographical ladder

People are using social media for different purposes and at different levels. Forrester Research Company [Li and Bernoff, 2011] has categorized the users of social media into seven categories and this is called the social technographical ladder (Forrester.com). Below is a table of the social technographical ladder [Li and Bernoff, 2011].

Table 1: the social technographical ladder (adopted from [Li and Bernoff, 2011])

Type of users	Activities
Creators	o Publish a blog o Publish your own web page o Upload videos you created o Upload audio/music you created o Write articles or stories and post them
Conversationalists	o Update status on a social networking site o Post updates on twitter
Critics	o Post ratings/reviews of products or service o Comment on someone else's blog o Contribute to online forums o Contribute to/edit articles in a wiki
Collectors	o Use RSS feeds o Vote for web sites online o Add tags to web pages or photo
Joiners	o Maintain profile on a social networking site o Visit social networking sites
Spectators	o Read blogs o Listen to podcast o Watch video from other users o Read online forums o Read customer ratings/reviews o Read tweets
In-actives	o None of the above

This research was based on the social technographical ladder which is highlighted in Table 1, to measure the impact of social media usage on one's self-esteem.

Self esteem

Self-esteem can be defined as positive self-evaluation or a broader concept of confidence. Positive self-evaluation indicates high self-esteem and negative self-evaluation indicates low self-esteem, this influencing the actions or the attitude of the person. Those who have high self-esteem follow goals actively and aggressively [Suzuki and Shunsuke, 2013].

Furthermore, self-esteem refers to the self or to specific areas of the self, for example their feelings regarding their social standing, their belongingness to a particular ethnic group, their jobs or school performance, their physical appearance, and so on [Wills-Herrera, 2014].

Self-esteem is very important in adolescence because without it or without sufficient amounts of it, the risk of a variety of adverse life outcomes will increase, including mental illness, substance abuse, aggressive and violent behavior, and early pregnancy and parenthood [Boden, 2011].

The Relationship between Social Media Use and Self-Esteem

Some earlier research found that there is a positive relationship between social media use and self-esteem when focusing on close friends and strong ties [Wilcox and Stephen, 2013] and the users had lower self-esteem when there was no interaction with social media [Jonas, 2013]. On the other hand some researchers could not identify the relationship between the use of social media and self-esteem. For instance, a study conducted with Asian international students found that the results of self-esteem correlated with academic achievement, and were not driven by excessive social media usage [Wu, 2013]. Furthermore, a study shows that certain personality traits have a strong effect on self-presentation on social media than self-esteem, because the big five personality traits (Openness, Conscientiousness, Extroversion, Agreeableness, and Emotional Stability) correspond well with

functions of social media. This conclusion was reached by observing Facebook and Twitter users based on the number of posts they did and the time they spent on these accounts [Zhang, 2015].

Another study measured the relationship between time spent engaging in social networking and individuals' self-esteem. The results indicated that individuals with lower scores on the Rosenberg Self-Esteem Scale spent more time on Facebook [Turner-August, 2015].

Another study has shed light on the behavior of online users, where it showed a possible relationship between the high usage of social media and higher levels of self-esteem [Crowell, 2015].

Research gap

The way people interact on social media differs from one person to another; consequently their self-esteem will be different. The previous studies focus on time spent on social media and its effect on self-esteem. Some of the studies focus on the type of social media used and the behavior of online users but they do not specify which types of activity the users are performing. Therefore, this study is aiming to categorize the users of social media based on the activities that they are performing most on social media. Then, the study will try to find the relationship between the different categories of social media user and their self-esteem through the following hypotheses.

Research hypotheses

In her article 'Improve your self-esteem with journaling' Fryer stated that you can increase your self-esteem by writing about positive things that are happening to you and, by concentrating on the positive, will end up by valuing yourself more [Fryer, 2016]. According to Forrester's research [Li and Bernoff, 2011], writing articles is one of the characteristics of creators social media users. Thus, it was hypothesized:

H1: Creators of social media possess high self-esteem.

Another study found that people who update their status frequently on social media received more social support from their followers [Keith Hampton, 2012]. Furthermore, Ma in his articles 'Understanding the psychology of twitter' [Ma, 2009] talked about the Maslow hierarchy of needs. He said that Twitter fails to meet people's social needs because people who tweet need to fulfill certain needs such as the need to belong and to be cared about. Once these needs are fulfilled people move to the higher level of the Maslow hierarchy of needs, which is self-esteem. Therefore, posting updates on Twitter will increase their self-esteem [Ma, 2009]. According to Forrester's research [Li and Bernoff, 2011], people who update their status on social media and post updates on Twitter are the conversationalists. Therefore, it was hypothesized:

H2: Conversationalists possess high self-esteem.

Yet another study found that commenting and discussing on online forums can promote your self-esteem. Consequently, your offline life will be positively affected [Rosenberg, 1979]. According to Forrester's research, commenting and contributing to online forums are the characteristic of critics. Therefore, it was hypothesized:
H3: Critics possess high self-esteem.

According to Forrester's research, tagging people to photos is a characteristic of social media users who are collectors. A study searched for the motivations of using tagging among people and found that people used tagging for being able to search and find people in the future, to express themselves and to comment on resources provided by others [Sa and Yuan, 2013]. Referring to collectors, commenting has a positive effect on self-esteem. Thus, it was hypothesized:
H4: Collectors possess high self-esteem.

An article by Westerholm (2013) stated that Facebook had a negative effect on self-esteem. This conclusion come from a study conducted on a group of people to measure their self-esteem while

visiting social media sites. It was found that, no matter what they were doing or how many friends they had, their self-esteem was still low [Westerholm, 2013]. Those who visit social media sites are called joiners. Thus, it was hypothesized:
H5: joiners possess low self-esteem.

Comparing your life with the life of other people through social media has negative effects on self-esteem [de Vries and Kühne, 2015]. When people read what others post and update in their profile, they feel less satisfied with their lifestyle, and consequently they will have low self-esteem [Williams, 2015]. Another study found that people have low self-esteem when exposed to other people's accounts who in contrast are posting positive updates and feeds [Tandoc Jr et al., 2015]. For instance, Instagram is based on photos that people share about their vacations or achievements. People who expose themselves to those photos think that other people are happier and more successful in their lives than they are [Winter, 2013]. People who view other's accounts and read their posts are called Spectators according to Forrester's research [Li and Bernoff, 2011]. Thus, it was hypothesized:
H6: Spectators possess low self-esteem.

Facebook has a negative effect on passive users who are not engaging in any activates such as sharing, liking and commenting [Highland, 1981]. Moreover, in a study conducted on a control group to measure their self-esteem while they used Facebook without participating in it found that those people had low self-esteem at the end of the study [Tobin et al., 2015]. The people who are not participating or carrying out any activities on social media are called 'In-actives'. Therefore, it was hypothesized:
H7: In-actives possess low self-esteem.

Research Methodology

The objectives of the study are to investigate the different types/categories of social media user and to investigate the relationship between using social media and its effect on self-esteem. To achieve this, certain steps have been taken. First of all, an intensive literature review has been carried out in order to understand the concept of self-esteem as well as to investigate the characteristics of social media, and the different types/categories of social media user. Based on this investigation a conceptual research framework was built, as shown in Figure 1 below.

Secondly, a research instrument (questionnaire) was designed and a pilot study was conducted to check the validity of the instrument. The main study was then conducted amongst the social media users in Oman to elicit information about the different types/categories of social media user based on the social technographical ladder, and their self-esteem according to the Rosenberg self-esteem scale [Rosenberg, 1979].

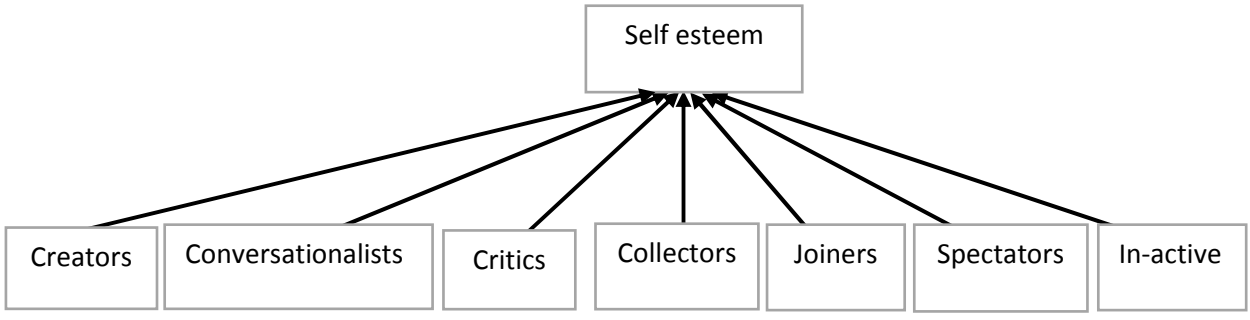

Fig 1: Research Conceptual Framework Diagram

The Rosenberg self-esteem scale

The Rosenberg self-esteem scale was developed by Morris Rosenberg [Rosenberg, 1979] to measure the self-esteem of people [Rosenberg, 1979]. It consists of a 10 item Likert scale type. It has five points scale ranging from 'strongly disagree' to 'strongly agree'. Five questions were positively worded statements and the other five were negatively worded. The self-esteem was then measured as follows:

- For Items 6, 7, 9, 11, and 12, ('Strongly agree' = 5, 'Agree' = 4, 'Neutral' = 3 , 'Disagree' = 2, 'Strongly disagree' = 1)
- For Items 8, 10, 13, 14, and 15, ('Strongly agree' = 1, 'Agree' = 2, 'Neutral' = 3, 'Disagree' = 4, 'Strongly disagree' = 5)

The score for each item was calculated. The total scores ranged from 10 to 50, and it was suggested that those who got a score of 30 and above had high self-esteem and those below that score had low self-esteem. The Rosenberg self-esteem scale was used in this study due to it's wide acceptance among researchers, for the brevity, reliability and validity of its results.

The research methodology that was adopted in this research is illustrated in Figure 2 below.

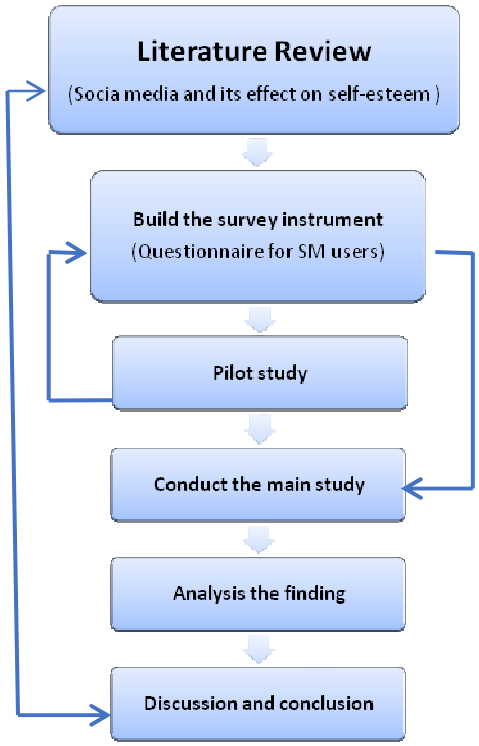

Fig.2: Research methodology diagram

The participants of the research were Omani people from different regions who were using different kinds of social media. The link of the online questionnaire was distributed via one of the social media (e.g.Whatsapp) using the snowballing method.

Data Analysis

The data were collected through the online survey. 97 social media users participated in this survey, 75.3% being female and 24.7% male. Table 2 shows general information about the participants.

Table 2: participant's demographic

		Frequency	%
Gender	Female	73	75.3
	Male	24	24.7
Age	<18	2	2.1
	18-30	73	75.3
	31-45	21	21.6
	> 45	1	1.0
Location	Al-Batinah	7	7.2
	Al-Buraimi	2	2.1
	Al-Dahera	52	53.6
	Al-Dakhileia	6	6.2
	Al-Sharqia	5	5.2
	Dhofar	8	8.2
	Muscat	17	17.5

The survey let the participants choose which category described them most accurately as a social media user. Table 3 shows the different categories of social media users.

Table 3: Social media users

Groups	*Frequency*	*(%)*
Creators	5	5%
Conversationalists	17	18%
Critics	7	7%
Collectors	8	8%
Joiners	12	12%
Spectators	39	40%
In-actives	9	9%
Total	97	100%

The statistical analysis used in this paper is ANOVA analysis. The output of the ANOVA analysis shows that there is no statistically significant difference between group means as determined by one-way ANOVA (F (0.436) = 6, p = .853).

Table 4: ANOVA Table

		Sum of Squares	df	Mean Square	F	Sig.
Self-esteem * SM users	Between (Combined) Groups	80.408	6	13.401	0.436	0.853
	Within Groups	2768.953	90	30.766		
	Total	2849.361	96			

Table 5 shows whether self-esteem is high or low for each category of social media user. All 'Creator' social media users have high self-esteem. So, too, do almost all Spectators and a significant majority of Conversationalist and Inactive users, whereas the self-esteem of Critics was more evenly balanced between high and low. However, overall over half of the users had high self-esteem.

Table 5: self-esteem (H indicates high self-esteem; L indicates low self-esteem)

Groups	*H (%)*	*L (%)*
Creators	100%	0%
Conversationalists	76%	24%
Critics	57%	43%
Collectors	63%	38%
Joiners	83%	17%
Spectators	90%	10%
In-actives	78%	22%

Discussion and Conclusion

This research aimed to investigate the different types/categories of social media user and to examine the relationship between different social media users and how social media affects their self-esteem. The research found that most participants were 'Spectator' social media users, while the least number of participants were from the 'Creator', 'Critic' and 'In-active' categories (see Table 3).

Upon analyzing the self-esteem of each category of social media user, the results revealed that all types of social media user (Creators, Conversationalists, Critics, Collectors, Joiners, Spectators and Inactives) indicated that they had high self-esteem. Therefore, the research hypotheses H1, H2, H3 and H4 were accepted, while H5, H6 and H7 were rejected.

Some of the limitations of the study reside in the number of participants. Also, the self-esteem study depends on self-reporting by individuals, so that there is a possibility that the participants are not accurate in their evaluation of themselves.

In brief, there are different categories of social media user. However, it is indicated that the use of social media has a positive effect on self-esteem, whether the users were active or passive in their use of social media.

Abstract

Within the context of public health protecting in the Czech Republic, the key law is the the law no. 258/2000 Coll.: "On protection of public health and amending certain related laws, as amended". To Human health is important to ensure quality and safe drinking water. The most important and comprehensive European Union's legislation is Water Framework Directive (2000/60/EC) of the European Union, which applies to all waters. The Czech Republic's or eventually European Union's population health status is influenced by a quality of drinking water, and water used for various purposes as well. The water is polluted by various substances, including remnants of drugs. The presented professional contribution is focused precisely on this subject, including some basic legal standards.

Keywords: European Union, Czech Republic, risks, drinking water, public health

Introduction

Act no. 258/2000 Coll. On protection of public health and amending certain related laws, in its basic concepts defines, among others, the notion of public health, public health risk assessment and more.

For human health is important to ensure safe drinking water. (*Rak Jakub, Jurikova Lucie, Sevcik David 2013).* Now mentioned Law on Protection of Public Health states that drinking water is all water in its original state or after treatment, which is intended for drinking, cooking, preparing food and drinks, water used in food industry, water, which is designed to body care, cleaning objects which by design come into contact with food or human body, and for other purposes of human consumption, regardless of its origin, state and manner of its delivery. Hygienic requirements for safety and purity of drinking water (hereinafter referred to as " the quality of drinking water ") is determined by hygienic limits of microbiological, biological, physical, chemical and organoleptic characteristics, which are regulated by the implementing regulation. *(Zákon č. 258/2000 Sb., o ochraně veřejného zdraví a o změně některých souvisejících zákonů). (Strohmandl Jan, Weinbergerova Silvie, Masek Ivan, Safarik Zdenek a*nd *Miroslav Tomek. 2015). (Strohmandl Jan, Tomek Miroslav, Masek Ivan and Taraba Pavel. 2015*). In terms of the European Union represents the Water Framework Directive (2000/60/EC), dated 23 October 2000, the most significant and comprehensive legislation in the area of water. The Water Framework Directive covers all waters - inland surface water, groundwater, transitional and coastal waters. Establishes the principle of a Europe-wide integrated approach for issues related to water quality and quantity, and regarding the issues of surface water, groundwater and for the water management the Directive introduces a management principle based on the unit of the river basin - in the Czech Republic this principle is implemented since the 60s of the last century. Water is therefore considered as a coherent whole. The primary objective of this policy is to achieve a "good status". *(Směrnice. Vodní rámcová směrnice 2000/60/ES).* To protect the population need to secure clean water. If this is not possible, then deal

with emergency supply residents with water. *(Musil Miroslav, Ludek Lukas a kolektiv. 2014). (Rak Jakub, Vicar Dusan, Tomek Miroslav, Svobodova Blanka 2015).*

Health and hygiene risks of water and the impact on public health

One of the problem areas that occurred in relation to the issue of drinking water in the Czech Republic are the remnants of pharmaceuticals in drinking water. Due to the reports of a possible presence of residues of pharmaceuticals in drinking water in the Czech Republic , which appeared in the media, the National Health Institute made its first horizontal mapping of pharmaceuticals in drinking water. In this first population-based screening of human pharmaceuticals in drinking water, carried out in 2009 - 2011 in a research project of GACR. „Occurence and health risks from human pharmaceuticals residues in drinking water ", five active substances were followed: naproxen, ibuprofen, diclofenac, carbamazepine and 17α - ethinylestradiol.

The substances were selected according their consumption greatest probability of occurrence based on the foreign and domestic findings or according the public anxieties based on media reports (the most feared hormone 17α - ethinylestradiol). The survey found that at the tap of the consumer , these substances occur very rarely, moreover in trace concentrations. In more than 100 sampled water supplies in three samples of two water pipes only, two of controlled substances were found in a concentration above the limit of quantification (LQ = 0.5 ng / l): three times it was ibuprofen (0.5 to 1.2 ng / l), one of carbamazepine (4.0 ng / l). When sampling in hazardous areas , that means at 23 water treatment plants that draw raw water to the middle or lower reaches of rivers , which are laden by wastewater , in the treated water at the plant outlet at 19 sites they were found one to three substances above the limit of quantification. Most seizures were with ibuprofen (16), followed by carbamazepine (11), naproxen (8) and diclofenac (3); concentration ranged from 0.5 to 20.7 ng / l, with medians below 6 ng / l. In the distribution network , however, they were collected from a values much lower, partly due to mixing with a ground water, probably partly due to chemical oxidation with chlorine.Amount of 17α - ethinylestradiol was in all samples under the limit of quantification (i.e. less than 0.5 ng / l, respectively less than 2 ng / l). For exposure to the detected amounts there is no known health risk because so-called Margins of Exposures comparing minimum daily therapeutic dose and a daily intake from drinking water, are in the order of thousands (7.5 x 10^3) 17α - ethinylestradiol (for exposure used theoretical value at the mid of LQ), respectively. in the order of 10^6 to 10^8 for other controlled substances .Favorable findings relate primarily to the structure of sources of water used for public supply in the Czech Republic, where half the water is produced from groundwater and most of the surface water is taken from protected reservoirs on the upper reaches of rivers. *(Státní zdravotní ústav (odpovědný řešitel za SZÚ: MUDr. Kožíšek). Grantová agentura ČR / číslo projektu: 203/09/1583. Výskyt a zdravotní rizika zbytků humánních léčiv v pitných vodách).* Based on the results of analyzes from 24 countries around the world, these showed that in some areas, particularly in the deltas of major rivers, the small remnants of drugs in water under certain circumstances may occur. Their condition is currently so low, that it becomes practically unmeasurable and can not have a concrete impact to human health . A statement that the water may contain residues of drugs is thus primarily psychological significance, not health. Drug consumption in the EU is constantly rising. Daily are utilized million packs of tenthousands drug kinds. They contain about 300 different active substances. Most often these substances are antibiotics, antidepressants, drugs for diabetes, hormonal contraception dampening pain or inflammation, cytostatics, beta blockers etc. The compounds of these drugs in the human body undergo metabolism. Some of them, however, are from the body still in active status excluded. On the other hand, many people destroys drugs with expired consumption by flushing it to toilet or throwing into the trash. According to the British research ends up in the garbage up to two thirds of expired medicines, into waste water gets up to fifth. Another possible form of water pollution by drugs are seepingfrom poorly secured landfills. To a lesser extent in some locations the pollution may be caused from waste or leaks during the process of pharmaceuticals production. In addition to human pharmaceuticals may be a partial answer to the water pollution as well the drugs applied to farm or domestic animals. In the process of waste water cleaning are substancesin medicines removed only partially, and in some cases hardly at all. In this way pharmaceuticals reach the surface and sometimes underground water, some of which may be a source of drinking water.

The ratio of drug concentrations at the inlet and outlet of the sewage treatment plant enables to identify pharmaceuticals that are removed during the cleaning proces at least. Regarding to the characteristics of these substances can not be assumed that their removal will occur during standard processes for drinking water treatment (aeration, sand filtration, disinfection etc.). More effective is absorption of the substances on activated carbon and ozonation. Even these processes, however, can not remove all of the pharmaceutical substances. To the presence of pharmaceutical residues in raw drinking water, the manufacturer must respond by adding a suitable degree of water treatment technology, if there is no other source of raw water. As an example can be used a water treatment plant in Amsterdam (Holland), where the source of water is located in an estuary of the Amstel river and an effective step in this water treatment plant is the membrane filtration (*Mohou nás ohrozit léčiva v pitné vodě?).* The question of the extent of water pollution by pharmaceuticals was gradually gaining more and more international attention.The project KNAPPE realised in 2008, (Knowledge and Need Assessment on Pharmaceutical Products in Environmental Waters) has mapped the occurrence of pharmaceuticals in the aquatic environment, totally 181 agents in 24 countries. The project was to process 58,600 data details, out of which the average value of a measured environmental concentration (MEC) was determined. The highest rate of pharmaceuticals water pollution was recorded in Germany. Out from all the data contained in the KNAPPE database, the vast majority relates to surface waters. Only 11% refers to the groundwater and 2.2% alone to drinking water. For the method of assessing the extent of the share of pharmaceuticals in drinking water and their potential risk still exist different approaches.

Any assesment method is chosen,while considered a worst-case exposure scenario, for any of evaluated substances was identified health risk in the context of detected concentrations in drinking water. In rare cases, the result can be described as nearly a borderline, but mostly the gap in several orders of concentration was identified, which could be described as human health affecting. However, data based on surveys abroad, can be used in the Czech Republic only partially. The volume and structure of pharmaceutical drugs consumption, the proportion of surface and groundwater use for drinking water production and water treatment used technologies varies from country to country considerably. It is therefore necessary to continue intensively in dealing with this issue in the Czech Republic. So far it is obtained very little data, mostly out of the locations which do not serve as a source for drinking water. In autumn 2009, was realised extraordinary analysis of water in Prague, where in addition to standard and regular checks of drinking water, the samples were also subjected to extensive testing on content of pharmaceuticals.

According to the analysis conducted by an accredited laboratory of state enterprise Vltava River basin - VHL Plzen, in all collected water samples, the compound of medicinal substances was in a such small quantities, that it was impossible even to determine them exactly. Laboratory samples were available from the water treatment plant Želivka of waterworks Káraný and directly from Prague's water supply, as well. (*Mohou nás ohrozit léčiva v pitné vodě?).* One of the kinds of substances that remain in the water after cleaning,are so called “PPCPs” (pharmaceuticals and personal care products)- the active ingredients of drugs. These are artificial, to the nature environment foreign substances (xenobiotics), whose degradation is problematic. They can be found in commonly used detergents, personal care products and of course in medicines. These active ingredients remain active even after they get into the waste water and then into the water cyrcle. There even in small quantities can cause great damage. Other unpredictable effects can arise by their synergistic effects or long-term accumulation in the environment. PPCPs problem is relatively new.

The boom of the pharmaceutical industry in its current form broke out after World War II. Mass drugs and personal care products use is the result of contemporary highly - developed civilizations ,for example we can mention Ibuprofen, the active ingredient in a variety of painkillers. Ibuprofen belongs to one of the most common used substances. Annual consumption in the Czech Republic is about 200 tonnes (plus about 10 tons of pure ibuprofen from illegal drug factories). Ibuprofen provides high stability and it is very difficult to be captured in a wastewater treatment plant. In the past, there were traces of ibuprofen captured in surface and ground waters. Small amounts of ibuprofen was measured recently in the tap water. Currently, however, not the amount that would endanger human health. Another group consists of antibiotics which are decomposed by UV radiation.This method is costly and it is uncertain what effect on other substances contained in the water it would have, therefore in sewage treatment plants it is not commonly used. Antibiotics used

in human and veterinary medicine and in various stages of decomposition penetrate into water and soil. Antibiotics present in the water and sludge deposits in addition reduce the effectiveness of friendly bacteria responsible for decomposition and nutrient cycling. Antidepressants in the Czech Republic in comparison to other countries do not use so often yet.Hormonal contraceptives are a separate group of drugs. They belong to a group of EDC (endocrine disrupting compounds) - substances that can interfere with glandular activity. In this case are meant, substances with estrogenic activity. This means that they imitate the behavior of the hormone estrone. Hormones were the first recorded physiologic substances in waters draining out of sewages. *(Veronica. Ekologický institut).*

Conclusion

This was only a brief overview and an excursion to the issue of drinking water, need to secure the high-quality of drinking water for the population of the Czech Republic , but also the European Union, if we talk about this issue only in a part of Europe. In terms of legislation I mention the basic standard, which is the Act no. 258/2000 Coll. “On the protection of public health and amending and supplementing some related laws”. Implementing legislation for the law On the protection of public health and amending certain related acts can be found in other source. *(Česko. Zákon č. 258/2000 Sb., o ochraně veřejného zdraví).* Under the term water treatment is understood the pollution elimination of the raw water, so as to obtain drinking water, that is sufficiently clean and suitable for human consumption. Regulation of the World Health Organization (WHO) are worldwide generally perceived as the requirements on drinking water quality. In addition to the WHO regulation, each country or region is able to apply their own standards. European countries must abide by the EC Drinking Water Directive. Selection of water treatment methods generally relate to the nature and availability of water resource and the standards set by local authorities. *(Pitná voda. Standardní model - chemická úprava). (Tomek Miroslav, Strohmandl Jan a Jakub Rak. 2014).* Decree no. 252/2004 Coll . in accordance with European Community law establishes hygiene limits for microbiological, biological, physical , chemical and organoleptic indicators of the quality of drinking water, including drinking water, bottled water, hot water supplied by piping, hot water or indoor water pipes, which are structurally interconnected using mixing water pipe with water supply pipe of drinking water and the hot water produced from an individual source for the personal hygiene of staff. The Decree also establishes the scope and frequency of checking compliance of drinking water quality, as well the requirements for methods checking the quality of drinking water. Drinking water must have such physico - chemical properties, that do not pose a threat to public health. Drinking and hot water should not contain micro-organisms, parasites and substances of any kind in the number or concentration that could endanger public health. Indicators of the quality of drinking water and hygienic standards are listed in Annex no. 1 of the Directive. For raw or drinking water, in which the treatment process is artificially reducing the content of calcium or magnesium, the magnesium content may not be after treatment of less than 10 mg / L and a calcium content of less than 30 mg / l. Radiological indicators of drinking water and their limits is determined by special legislation. This legislation regulates the sampling of drinking water and the sampling points. Samples of drinking water, are taken to a control in a manner so that they are representative of a drinking water quality consumed throughout the year and for the entire water supply network, as well. The number of sampling points must at least be equal to the number of shortened analysis according to Annex no. 4, by water supply systems supplying more than 5,000 inhabitants, the number of sampling points must be equal to at least 80% rate of shortened analysis according to the Annex no. 4. The sampling sites should be selected so that more than 50% of the sampling sites were not permanent, but changed each year. Changing sampling points shall be chosen by random selection or any other suitable method that ensures that none of the buildings supplied will be excluded from the possibility of control. Sampling of drinking water is done in places where they should be met water quality requirements (§ 8). In the case of antimony, arsenic, benzene, beryllium, boron, bromates, nitrates, fluorides, chlorides, cyanides, microcystin LR, ozone, pesticidal substances, mercury, selenium and sulfates in which it is not anticipated that their concentration could during distribution between the converter and the point of consumption increase, can be samples of drinking water taken either at the plant outlet

or at appropriate places of water supply network , such as reservoirs, if it demonstrably do not produce changes in the measured values of the indicator. (*Česko. Zákony. Vyhláška č. 252/2000 Sb*.).

Law no. 378/2007 Coll., on Pharmaceuticals, as amended in §88 and §89 provides operators of pharmacies obligation takeover of unusable drugs and drugs of unsatisfactory quality,with expired shelf life, stored or prepared under other than specified conditions, obviously damaged or unused (unusable drugs) must be disposed off, including their packaging, so as not to endanger human life and health or animal health or the environment. When handling unusable drugs shall be treated as the handling of hazardous materials, including lead their evidence under special legislation. Unusable transfusion products and products for advanced therapy, are disposed off as waste, whose collection and disposal is subject to special requirements in order to prevent infection.Disposal of unusable pharmaceuticals are conducted by legal persons or individuals on the basis of consent granted by the regional authority in delegated competence or, in the case of radiopharmaceuticals, by the State Office for Nuclear Safety. About granting consent informs the authority which granted the approval, the Ministry of Health , in the case of human medicine, or the Ministry of Agriculture in the case of veterinary medicine, and communicated information includes the name of the process equipment serving the disposal of unusable drugs, operated by a legal person or an individual.Operators are obliged to hand over unusable pharmaceuticals to the persons referred to §88 paragraph 3. Unusable medicines handed over by individuals to the pharmacy, must be accepted and the pharmacy is obliged to overtake them. The costs arised to a pharmacy to drop off drugs to persons referred to in §88 paragraph 3. and with their removal executed by these persons, is paid by state through the regional office. (*Státní ústav pro kontrolu léčiv. Převzetí nepoužitelných léčiv k likvidaci*). It should be noted that the relevant legislation in this area are for example: Law no. 185/2001 Coll., On waste, the Decree no. 383/2001 Coll., On details of waste management, and law no. 500/2004 Coll., Administrative Procedure Code, and more. Although the situation of water pollution in the Czech Republic through the drug residues is not alarming,it should be noted that this situation may become an important society-wide risk and may result in a significant deterioration of the health status of our population. Contamination of drinking water affects the production of safe food, beverages and quality of the environment on our planet. *(Lukaskova Eva, Pitrova Katerina, Taraba Pavel a Helena Velichova. 2015). (Chlachula Jiri, Sefcik Vladimir a Eva Lukaskova. 2012).*

Abstract

Internal audit departments are more than ever before pressured to reduce costs and become more efficient. The use of IT has proven to be a suitable means to achieve this efficiency gain, but also holds limits in the audit area. One approach which tries to overcome these limits and has gained popularity over recent years is the concept of continuous auditing. Continuous auditing deals with the highly frequented or even continuous testing of diverse business activities by means of identifying exceptions or abnormalities, partly with assistance of technology. It may be applied to any kind of data and helps the auditor to focus his manual audit activities on areas with high risk. Despite its potential, we find that companies refrain from using continuous auditing on a large scale which is supported by a range of other studies. This is mostly because of its high implementation efforts and the limited availability of corporate data in digital form. Still, continuous auditing represents a promising supplement to traditional auditing which may more and more enter daily audit practice and change auditors' operational work towards a more automated, risk-oriented approach in near future.

Keywords: continuous auditing, internal audit, internal controls, risk management

Introduction

Although the general focus of internal audit work and its underlying objectives have more or less remained the same, auditing methods used by internal audit departments have advanced over time. Latest developments as the growing digitalization of business operations and the growing extent and diversity of data handled in these operations require from auditors to adjust their audit work and make use of sophisticated methods to handle these challenges. The usage of IT as audit support mechanism has become popular among the audit functions of many companies over the last decades and looks back at a considerable development.

The first steps towards IT usage in internal audit were already made in the 1960s when companies started developing and implementing audit modules which were embedded in legacy systems. As IT was a relatively young topic back then, administration of embedded audit modules was both costly and challenging. Therefore usage was not very wide-spread.

In the 1980s, computer-assisted audit tools and techniques (short: CAATTs) gained in popularity and were used for data analyses and ad hoc investigations. To a large extent, however, the audit profession lacked technical skills, suitable software tools, as well as the organisational will the overcome the challenges coming alongside with this new audit approach.

In the 1990s data analytic solutions were introduced and increasingly used by the internal audit function to verify data and controls. Despite the solutions' potential to analyse data and control on a large scale, auditors refrained from testing whole populations and kept relying of samples (Coderre, 2005).

Nowadays, companies are pressured to reduce costs wherever possible more than ever before. As this development applies to all departments of companies, internal auditors have to find efficient

solutions to reach their audit opinion without a loss in quality. The growing amount of corporate data and its increasing heterogeneity makes this task even more challenging.

One audit methodology which tries to tackle this challenge and increasingly enters businesses' practice is the concept of continuous auditing (short: CA). CA deals with the highly frequented or even ongoing testing of diverse business activities by means of identifying exceptions or abnormalities, partly with assistance of technology. The auditor is thereby directed to areas of increased risk for further (manual) audit activities. Areas without noted exceptions are left out of consideration for further actions. Thereby, it is possible to audit the full extent of a population (instead of only a sample as under the traditional audit approach). By this significant change in the audit approach itself, CA aims at leveraging internal auditing to a higher maturity level.

The academic article at hand focuses on the question in how far CA represents the future way of auditing. It will elaborate on the components of CA, its aims, its subareas, as well as its advantages and disadvantages. Also, it will explore where companies currently stand on their way from traditional auditing to continuous auditing.

Continuous Auditing in detail

Definition

The concept of CA was first introduced by Groomer and Murthy (1989) as well as by Vasarhelyi and Halper (1991) about 25 years ago. According to CIPA/AICPA (1999), this concept covers "a methodology that enables independent auditors to provide written assurance on a subject matter using a series of auditors' reports issued simultaneously with, or a short time after, the occurrence of events underlying the subject matter".

This definition implies several aspects. Using CA in an effective way presumes that the subject matter to be audited has previously been analysed in its design and that appropriate auditors' reports have been identified. Auditors' reports thereby take the form of measuring points (e.g. key performance indicators (short: KPIs), key risk indicators (short: KRIs)) and may focus on a set of selected controls, risks, or on data in general to verify a specific subject area. For each measuring point, target values need to be in place in order to serve as reference values for the factual measurement results at a later point in time. Both measuring points and target values have to be set in a way in that they enable the auditor to make proper conclusions about the subject matter's state. As this preparatory work is rather time- and cost-intense, it is advisable to concentrate on the most critical subject matters only and to choose not more measuring points per subject matter than ultimately necessary. Thereby, the specific amount of measuring points largely depends on the complexity of the subject matter and the degree of assurance to be achieved by the auditor.

The aim of providing written assurance to an addressee (usually top management, the board of directors, or the audit committee as part of the board of directors) as quoted in the definition of CA is the same as under any other audit approach. Also, the definition leaves open the degree of assurance to be provided. In general, assurance provided by continuous auditing may be reasonable or limited. However, due to the high initial input to implement CA, it is advisable to aim for limited assurance only and to complement CA with additional audit activities to achieve a higher level of assurance.

The definition also implies that auditors' reports are issued (i.e. evidence is gathered) simultaneously or shortly after the occurrence of events underlying the subject matter. Therefore, measurement of subject matter may need to take place in a highly frequented, if not continuous manner. CA per definition does not require IT to support the audit process, but computer assistance during the measurement process is highly recommendable to keep the methodology time- and cost-efficient.

In contrast to traditional auditing which features periodic reviews of only a sample of a subject matter, continuous auditing covers an ongoing audit testing of 100 % of all relevant data of a subject

matter. Thus, it provides auditors with an opportunity to go beyond the limits of traditional audit approaches and the limitations of sampling (Chan and Vasarhelyi 2011).

Subareas
According to Vasarhelyi (2011), CA comprises three subareas:

- Continuous Data Assurance
- Continuous Controls Monitoring
- Continuous Risk Management and Assessment

Continuous Controls Monitoring covers the ongoing assessment of internal controls. These controls may originate from different departments as finance, IT, accounting, or personnel and may cover different hierarchy levels. By using Continuous Controls Monitoring, the auditor obtains an early indication about the existence of potential weaknesses in theses departments, as well as in the departments' structures and processes. To identify any weaknesses, KPIs are used to measure whether controls have been executed and whether the execution was performed in line with time targets (Vasarhelyi, 2011).

Continuous Risk Management and Assessment refers to the activities used by auditors to identify and assess the levels of risk or changes to the level of risk. Thereby, KRIs (rather than KPIs) measure abnormalities in departments, processes, or IT systems. Most importantly, these KRIs need to be of forwards-looking character, i.e. they indicate developments which may cause a risk to arise or to change negatively in near future (Vasarhelyi, 2011).

Continuous Data Assurance includes all other activities by auditors to verify data on an ongoing basis. In most cases these analyses feature data at transaction or account level, but may also cover data from more aggregated levels. Thereby, Continuous Data Assurance uses KPIs to identify undesired developments in chosen subject matters which are not primarily considered as control or risk, e.g. continuous scans of master data changes, authorizations and parameters in IT systems, or transaction data (Vasarhelyi, 2011).

Due to the wide range of application areas, also the aims of CA can be manifold. In general, CA can follow the same objects as ordinary audits (e.g. financial audits, operational audits, compliance audits, forensic audits). Thereby, the ability of an internal audit department to rely of CA largely depends on the digital availability of subject matter data as well as of the objectives to be achieved by the audit (Abdolmohammadi and Sharbatouglie, 2005; IIA, 2013).

Procedure
Several approaches have been discussed in literature to introduce and operate CA. These range from high-level phase models to delicate process flows (e.g. Abdolmohammadi and Sharbatouglie, 2005; Mainardi, 2011; IIA, 2015). Few of these approaches also consider CA as some kind of ongoing cycle (e.g. Yeh and Shen, 2010). To work effectively, changes to companies as well as to their internal and external environments need to be accounted for frequently when using CA. Therefore, we agree with Yeh and Shen that CA is an ongoing cycle which constantly identifies potential for its own optimization.

Irrespective of the specific subarea CA is used for or its individual objective, this cycle approach can be broken apart into four phases following the plan-do-check-act cycle.

The *Plan*-phase is of decisive importance, especially during the first-time introduction of CA. During this initial phase, objectives to be achieved as well as the desired level of assurance to be obtained by using CA should be defined. Also, the subject matters to be analysed by CA need to be determined. These can range from specific detail matters to processes, IT systems, or complete departments and corporate functions. Choices made should be based on a medium- to long-term, risk-oriented audit planning. Subject matters which usually require an increased level of manual audit activities may be preferably chosen for CA as these offer an increased potential for efficiency gains.

In accordance to the previously set objectives, measuring points (i.e. KPIs/KRIs) need to be defined for each subject matter. These represent the basis for measurements performed at a later phase. The definition of KPIs/KRIs usually turns out to be a challenging task as their quality directly influences the explanatory power of CA results. As KPIs/KRIs express a specific matter in condensed form, valuable information which would have been gathered during a manual audit, may be lost. Auditors therefore tend to compensate for this risk by defining a considerably high amount of KPIs. Contrarily, the administration (i.e. the actual measurement) of KPIs/KRIs binds financial resources and should therefore be limited to a minimum. Thus, a general amount of measuring points is difficult to state as the extent of KPIs/KRIs depends on the complexity of the subject matter and the desired degree of assurance. To find a suitable solution, it is advisable to analyse the subject matter in its design before designing measuring points.

Moreover, appropriate measurement frequencies for data transmission need to be set. These do not necessarily be perfectly continuous, but should be in line with the CA objectives.

For each KPI/KRI, target values need to be defined which will later be used as reference to measured values. These target values should be set in a way that they allow the auditor to make meaningful conclusion about the audited subject matter. If target values are set too high or too low, exceptions may either me identified in excess (so-called *false positives*) or may not be identified at all.

Follow-up activities which are to be performed upon identification of an exception should be defined in this stage as well. In practice, it turns out useful to document these proceedings and provide them to the employees in charge of carrying out follow-up activities. Optimally, this documentation does not only include activities to be performed, but also points out responsibilities, time lines, etc.

The *Do*-phase includes the actual analysis and evaluation of data. In specific, KPIs/KRIs are determined based on collected data at previously defined points in time. The exact course of action depends on the previously set objectives and the extent of CA activities as well as on the company's technical capacity. It may comprise the following tasks:

- Data selection
- Data extraction
- Data storage
- Data harmonization
- Data preparation
- Data analysis

At first, required data needs to be identified at the place of origin. This identification may turn out to be rather challenging, if relevant data is part of a larger data set and not separated from irrelevant data. In this case, relevant data needs to be marked off before it can be used for further purposes. This delimitation may be based on different parameters (e.g. time, range, content, key words) and should be used to make the data selection as suitable as possible to what is needed for later analyses.

Selected data needs to be extracted and transferred to the entity performing the audit. Hereby, it must be ensured that original data is not changed and that only a duplicate of the original data is transferred. The audit entity may be an auditor (in case CA is performed manually), an audit module which is integrated in the legacy system holding the subject matter, or a separated audit system (Kuhn Jr. and Sutton, 2010). The transferal itself may vary from the auditor transferring data on a storage device to data being transmitted automatically via a technical interface between legacy system and audit module/system. Once transferred, data should be stored and not modelled in any way in the further process. Instead, data analyses should be done with further duplicates of the stored data. Before analyses may actually be performed, data needs to be prepared. This preparation may include steps as grouping, restructuring, or filtering. When data is drawn from different data sources or turns out to be heterogeneous by nature for any other reason, harmonization of data is an essential element

of this stage. Hereby, it is irrelevant whether CA is performed manually or automated (by means of an audit module or an audit system).

These single steps are not necessarily obligatory and may vary in order. If carried out manually, they steps usually turn out to be rather time-consuming. Using IT software to automate proceedings may therefore yield significant benefits.

After measurements have been made for each KPI/KRI, results can be compared to previously defined target values in the *Check*-phase. If tolerance levels were defined, these are to be considered accordingly. Depending on whether CA is performed in a manual or automated manner, results may be presented in various forms. In audit modules/systems, identified derivations between measured values and target values are usually shown as alerts. Some audit modules/systems also make use of traffic light diagrams (red, yellow, green) or two-level scales (pass, fail). Irrespective of the actual form, it is advisable to display results as clearly as possible to simplify identification of areas needing further attention.

Follow-up activities to be performed in the *Act*-phase may vary in form and extent and may range from analytical procedures to case-by-case activities as inspections, inquiries, observations, or reperformances. Findings won by these follow-up activities should be used for verifying previous results from CA activities as well as for reaching (or strengthening) audit opinions. Also, they should be used for optimising KPIs/KRIs, measuring frequencies, target values, and tolerance levels for future CA activities. Follow-up findings may also be useful to reevaluate subject matters' appropriateness for CA purposes. If adjustments are made to the CA methodology, corruption of previous results should be prevented.

CA adoption

Maturity models

In academic literature, some authors assume CA to be the ultimate maturity stage of internal audit (e.g. Chan and Vasarhelyi, 2011; Vasarhelyi, Alles, Kuenkaikaew, Littley, 2012). Thereby, the underlying assumption is that the internal audit function of a company matures over time and becomes more and more sophisticated in its structures and processes. Briefly speaking, maturity models used in literature mostly hold four (in some cases also five) stages, starting with uncoordinated audit activities and ending with strictly structured, automated audit activities (e.g. traditional – emerging – maturing – full continuous). To determine the maturity of an audit function and its belonging to a specific stage, several dimensions are quoted in literature. Among the most frequently mentioned dimensions are the following:

- Objectives
- Extent
- Time frame
- Data access
- Automation
- Audit and management overlap
- Diversity and management of audit subfunctions

The objective and the scope of auditing activities already give an indication about the maturity of an internal audit function. Traditional auditing usually includes a long-term planning which set forth single audits aiming at obtaining assurance about very specific subject matters. CA meanwhile aims at an area-wide coverage of a range of subject matters and only assumes detail testing to happen if exceptions are identified during previous CA analyses. Also, audit activities covering large data volumes may preferable be found in CA.

Traditional auditing is usually centred on drawing meaningful samples from a defined population. Therefore, audit results largely depend on the sample and may be distorted if sampling methods are

applied inappropriately or simply by sampling bias. CA overcomes these shortages by taking into consideration the full population and ensuring a 100% coverage.

The traditional audit approach may include periodic audits as well as irregular audits and ad hoc audits. Due to their nature, audit results are obtained some time after the event has occurred and therefore bear the risk of being obsolescent. Based on this time gap, unfavourable events may already have caused damage to the company without the auditor having the opportunity to counteract. CA, instead, is highly frequented or even follows a real-time frequency. Audit reports are provided to the auditor immediately or shortly after the event's occurrence. The auditor can therefore act on short notice and cure identified exceptions before it causes serious damage to the company.

The reputation of the internal audit function within a company largely determined the power it has over other departments and the extent it can push through its interest. Internal audit functions with limited internal power may face the problem of having only limited access to required data. This may be a result of other functions refusing to provide access or granting access only after formal requests (with upper management involvement) have been posed. Under CA, the audit function comprises of unlimited or almost unlimited access to all corporate data. If necessary, access to data is granted on short notices without much organisational resistance.

Traditional auditing makes only limited use of technology. For the most part, audit planning is done without IT assistance and audit activities are performed manually. Audit reports are typically stored in hard copy. The usage of technology generates large efficiency gains under CA and is therefore highly recommended. This IT usage is not limited to audit activities only, but may also cover audit planning at a previous phase as well as the audit documentation at a later phase.

Let alone any regular (obligatory) reportings of the internal audit function to management, the audit function operates independently from management under traditional auditing. Cooperation between these two parties hardly takes place and coordination of audit scopes or objectives in specific are rare. Under CA, audit activities go hand in hand with management's activities. Planning is largely harmonized, areas which are of less interest for management are preferable covered by the internal audit function. Due to this close integration, one function makes use of the other's results. Also, the audit function may verify management's activities.

Audit activities under tradition auditing are centred on financial aspects. Other aspects, e.g. IT, compliance, data security, are only audited with less priority. Also, if these „minor" areas are subject to an audit, this audit is largely independent from other audits and is seldom interlinked. The situation is the complete opposite under CA. Finance is not necessarily the central subject matter to be audited. Instead, audit activities are well spread over diverse topics and cover a wide range of areas as compliance, security, IT, and operational aspects. Audit activities are interlinked and complement each other in formulating an audit opinion.

Degree of CA adoption in practice

A lot of research has been undertaken to find out in how far companies have adopted CA and where they find themselves in diverse maturity models. As these studies differ considerably from each other in terms of research approach, used data, and timing, results vary significantly as well.

The studies by PricewaterhouseCoopers of 2006 as well as by ACL and the Institute of Internal Auditors (short: IIA) of 2009 indicate that the use of continuous auditing in practice is wide-spread. However, as both studies do not provide a deep insight into the actual intensity of continuous auditing usage, these articles leave some doubt in regard to the representativeness of their findings.

Vasarhelyi, Alles, Kuenkaikaew, Littley (2012) also dealt with this issue and, amongst others, brought forwards the objective to find out about the state of adoption and implementation of continuous auditing systems by internal auditors. On a general level, the authors conclude that companies which had participated in their survey find themselves between stages 1 (traditional) and 2 (emerging) in regard to the level of continuous auditing adoption which clearly contradicts the

findings of the PricewaterhouseCoopers study and the ACL/IIA study. Given this observation, they conclude that perceived usefulness of continuous auditing is rather low.

In their article of 2012, Gonzalez, Sharma, Valletta primarily deal with the antecedents of the use of continuous auditing in the internal audit context, but also analyse the extent of usage of CA. By performing a regression analysis they find that only few companies have continuous auditing fully implemented.

Our experience from the practical field in Germany reflects the rather low implementation rate of CA. Many companies we have worked with over recent years have implemented IT tools to analyse subject matters as part of their audit activities. Mostly we find that these tools are used in irregular intervals based on specific needs as part of scheduled audits (e.g. fraud or authorization scans for specific divisions or departments). However, only in very rare cases companies apply these tools as part of ongoing/continuous audit activities or to provide real-time assurance. Notably, the implementation rate is relatively higher at larger companies than at medium and small companies.

In various talks with members of the internal audit function, we verified the reasons for the low implementation rate and concluded a range of factors hindering the spread of CA. Mostly quoted, the initial implementation of CA requires a high level of cost and time. Before KPIs/KRIs can be defined as basis for measurements, it is recommendable to analyse the subject matter in its design. Otherwise, KPIs/KRIs may lack in precision and may fail the meet CA objectives. Also, target values may not be set appropriately, leading to either exceptions not being identified or to events being identified and labelled as exception while in fact they are unsuspicious. Also, some companies figured that digitalization of their structures and processes had not advanced far enough to enable data to be provided on an ongoing basis. Other companies meanwhile lacked of monetary funds to finance the acquisition or development of an IT system to support CA. In rare cases the audit function saw itself not experienced and knowledgeable enough to tackle the challenges accompanying the implementation and maintenance of CA (e.g. missing experience with specialized IT systems).

Conclusion

Used in an integrated manner, CA enables auditors to identify and remedy weaknesses. Moreover, it turns out to be more time- and cost-efficient than the traditional audit approach. CA features audit coverage of full data populations and therefore overcomes sampling bias of traditional auditing. Before CA is implemented, it is highly recommended to analyse subject matters in their designs in order to ensure a proper definition of measuring points. Among all involved employees, these analyses increase the general understanding of the companies' internal structures and processes as well as their external environments. Also, using KPIs/KRIs allows the auditor to focus on critical areas in a risk-oriented manner which frees resources bound to other areas under the traditional audit approach.

However, these benefits come at a cost. Irrespective of the specific architecture (embedded audit modules, separate audit systems), using IT for CA purposes requires investments for acquisition or development of software as well as for maintaining and updating software in regular intervals. While the IT systems only display auditors' knowledge and experience, the auditor needs to be knowledgeable about subject matters to be audited. This implies that the auditor keeps spending time on analysing subject matters even after the initial CA implementation in order to continuously guarantee a proper definition of measuring points, target values etc. Thereby, the auditor's IT affinity plays a decisive role. During the initial implementation of CA, efforts to be taken may turn out to be higher than under regular usage in later years.

Still, CA includes elements showing promise to make the audit function both more effective and more efficient in future. Given the rather high challenges during its implementation, most companies will refrain from introducing CA for all performed audit activities at once. Correspondingly, benefits generated from the use of CA will not be reached on a short-term basis, but are the result of a

constant step-by-step process towards a higher level of automation and an increased concentration on risk.

Provided that manual audit activities will remain necessary, especially as part of follow up-activities during the *Act*-phase, CA does not represent a completely true alternative of traditional auditing. However, it does represent a valuable complement to traditional auditing which will significantly change the internal audit function. Manual and continuous auditing activities will become more interrelated over time. Manual activities by the auditor will be highly dependent on results of CA and vice versa. This will also impact the auditor in his daily working routines. Focus will shift from highly operational activities as single-case reviews and analyses to more analytical activities as audit planning, managing KPIs/KRIs, and technology handling. Moreover, risk will even more be the leading factor of choosing audit subject matters.

The Development of Process-Based Information Systems: Methodological Requirements

José Luís Pereira, Jorge Oliveira e Sá
Universidade do Minho & Algoritmi, Guimarães, Portugal, {jlmp,jos}@dsi.uminho.pt

Abstract

At the present time several issues are dramatically challenging the way we build and maintain information systems. On the one hand, owing to the extremely competitive conditions and dynamics of the business environment, it is vital for organisations to be able to develop and modify their information systems as quickly as possible, in order to succeed or even to keep in business. On the other hand, new technological developments have recently brought to the information systems infrastructure a set of new technologies with enormous potential to improve the way information systems support organisations. Collaborative technologies and, in particular, workflow, are notorious examples. In this paper, we propose a new information systems framework (Process-based Information Systems), which is able to provide organisations with the means to respond timely and adequately to the opportunities and threats of the business environment. Regarding this framework we try to identify the limitations of conventional Information Systems Development methodologies and, therefore, propose a set of new methodological requirements.

Keywords: Process-based Information Systems, BPMS, Collaborative Applications, Component-based Architectures

1. Introduction

It is generally accepted that organisations have never had the information systems they need to properly conduct their business. Nowadays, the situation is getting worse. Due to the globalisation of the markets, the competition and the pace of change in business have increased to levels never seen before (Hernaus, 2011). To succeed, or even to survive in this turbulent environment, organisations must be flexible, innovative and react quickly and adequately, as a whole, to the constantly changing conditions of the markets (Rosemann and vom Brocke, 2015). Obviously, in this demanding scenario, the pressure put on the information systems' development and maintenance activities is higher than it has ever been.

Nowadays, more than ever, organisations need Information Systems Development (ISD) methodologies that deliver quick, adequate, integrated and easily maintainable systems, which take the maximum advantage of all the information technologies available today. Unfortunately, organisations continue to receive inadequate systems, which are delivered late, require large maintenance efforts and are typically disconnected from the other systems already in operation – the widely known "*islands of automation*" (Liao and Tu, 2007).

Clearly, a new information system concept is needed. A new information technology infrastructure has to be defined; one that makes full use, not only of the more conventional information technologies, but also of the emerging collaborative technologies (Pereira, 2004). Additionally, a new approach to the development of information systems build over this technological infrastructure has to be defined.

Concerning this paper's organisation, in the next section we present some justifications for the actual panorama of information systems in organisations and argue for new ISD approaches. In the third section we describe, very briefly, the fundamental characteristics of the groupware and workflow technologies, which are fundamental to our proposal. In the fourth section we define the proposed information systems framework that will provide organisations with the means to succeed in today business environment. In the fifth section we identify the limitations of current ISD methodologies regarding the proposed framework and define a new set of methodological requirements. Finally, in the sixth section we conclude.

2. The Need for New Approaches to Information Systems Development

As defined by Brodie and Ceri (1992), an information system "*consists of a collection of applications that implement required functions (representing state retrievals and changes) over a collection of shared, persistent information repositories (representing the pertinent aspects of the state).*" In this conventional perspective, an information system consists of a collection of related computer-based artefacts (applications and data stores) developed to support an identified set of required functions.

Despite all the efforts around Information Systems Planning (ISP) in the past, the development of information systems in organisations has originated, almost invariably, a collection of autonomous, independent and poorly connected systems, whose mission is to support the information processing needs of each organisational unit, independently from the others. Moreover, as each organisational unit has some degree of decision autonomy and is separately managed, it is not uncommon to find in the same organisation several systems, developed with different technologies, sometimes very difficult to make compatible. For those reasons, as already mentioned, nowadays the information systems organisational landscape is made up of what is commonly known as "*islands of automation*" (Liao and Tu, 2007). Of course, this fact has undesirable consequences in terms of a non-integrated view and treatment of the organisation's information assets and operations.

This situation has historical justifications, some of organisational nature and some of technological nature. On the one hand, owing to the predominance of the functional model on which the organisations were structured, it is natural that the development of information systems should have been conducted according to the same paradigm, resulting in information systems that support the processing requirements of single functional units. On the other hand, as a consequence of the evolution occurred within the information and communication technologies, solutions that are now easy to conceive, were previously not even thinkable. In other words, the developed information systems have also been constrained by the technological possibilities of the time they were built.

Obviously, the ISD methodologies should be adapted, at every moment, to the characteristics and requirements of the organisations they are going to be applied to, and also to the emerging functionalities made available by the Information and Communication Technologies (ICT). In other words, the ISD methodologies must be permanently aligned with the organisational and technological circumstances of the moment. Regarding this matter, there have recently been some significant changes and advances both on the organisational and technological domains.

In the organisational domain, since the beginning of the 90's, and most notoriously with the work of Davenport (1993) and Hammer and Champy (1993), a new organisational paradigm has begun to take shape, associated with a set of organisational change programmes, among which the most widely known today is *Business Process Management* (BPM) (Rosemann and vom Brocke, 2015; Weske, 2012; Trkman, 2010; Dumas et al., 2013).

Contrarily to the hierarchical and functionally structured organisations, based on the Tayloristic model of work division, which was the standard organisational structure in the past, the concepts of *organisational process* (also known as *business process*), *teamwork* and people *empowerment* have emerged as the new paradigm on which the organisations should be based (Pereira, 2004). This new paradigm which promotes an integrated view of the organisations, is expected to prepare them to react adequately to the rapidly changing conditions of today's markets.

In the technological domain, as a result of the remarkable developments in the hardware and data communications fields, a set of new technologies, globally known as *groupware*, or *collaborative technologies*, has emerged. These technologies are primarily intended to support the communication and collaboration needs of people working together and thus, may help to achieve the integrated information systems infrastructure (Li et al., 2015).

This set of new technologies, also known as CSCW (*Computer Supported Cooperative Work*), is increasingly being used by organisations, as they understand that, today, sharing information and working in teams is the most effective way of doing business (Coleman, 1997). One of those technologies – *workflow* – is particularly suitable to support the co-ordination of work according to an organisational process.

Unfortunately, groupware technologies are being introduced into organisations in a very ad-hoc way, preventing them from taking full advantage of these technologies (Li et al., 2015). Obviously, the groupware technologies, in the same way as the more conventional information technologies, are going to be part of the global information systems technological infrastructure and so, they should be involved in the overall information systems development effort right from the beginning.

Besides the new paradigm which organisations are being forced to adopt in order to succeed in the market, and the new technological infrastructure available, another issue with a huge impact on the way information systems are developed is the rate at which the business environment is changing nowadays. In the past, even when the markets were stable and the levels of competition were moderate, the ISD methodologies in use were already incapable of delivering adequate solutions on time. In fact, that was one of the most often heard criticisms about ISD methodologies. Today, owing to the dynamics of the business environment, the situation is much more complicated. Indeed, if organisations keep on using those conventional ISD methodologies, they will end up with an even greater information systems backlog.

Of course, the same problem exists regarding information systems maintenance. Organisations must be able to change their information systems in a very rapid way, otherwise they will not be fast enough to react timely to the opportunities and threads that are continuously appearing.

In an effort to support the organisations more effectively, the ISD methodologies must take into account the facilities provided by the new technologies, the dynamics of the business environment and the new organisational paradigm (Pereira, 2004) (Fig.1).

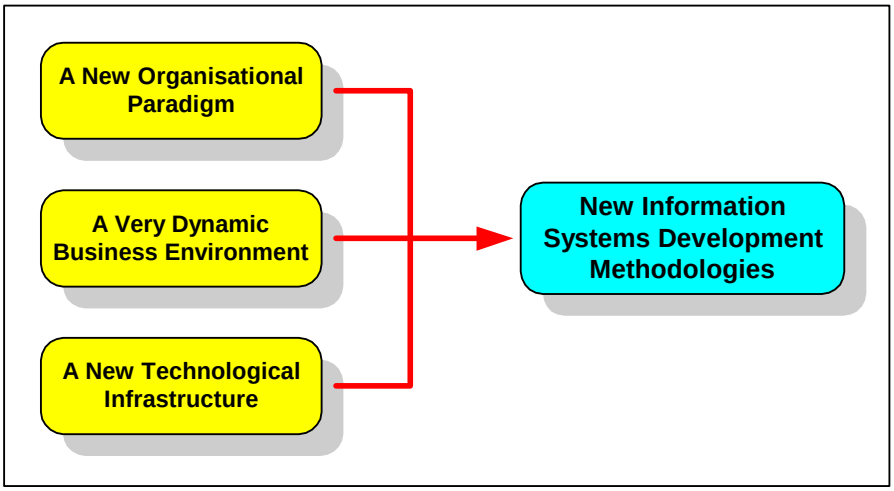

Fig. 1: The need for new ISD methodologies

Nowadays, despite the huge number of ISD methodologies available (already in the nineties Avison & Fitzgerald (1995) mentioned the so-called "methodologies' jungle"), none of them takes into account these new and radically different organisational and technological environments, as they were developed with the specific organisational conditions and technological targets of the past in mind, and now fail to cope adequately with the new development environment. Obviously, the ISD methodologies should be adapted to the new organisational and technological context. In a sense, they need to be reviewed and adjusted to the new realities.

3. Collaborative Technologies

Groupware was defined by Ellis et al. (1991) as "*Computer-based systems that support groups of people engaged in a common task (or goal) and that provide an interface to a shared environment.*" The principal objective of this set of technologies is to facilitate the interaction between people working together, making them more effective and efficient. Electronic mail, videoconference, team

rooms, group editors, discussion groups and workflow systems are just some examples of groupware technologies (Li et al., 2015).

A commonly used classification for the various groupware technologies is Johansen's Time/Space Matrix (Johansen, 1994). This classification tries to distinguish among the different groupware technologies, classifying them in time (synchronous/asynchronous) and space (centralised/distributed) dimensions (see Fig. 2).

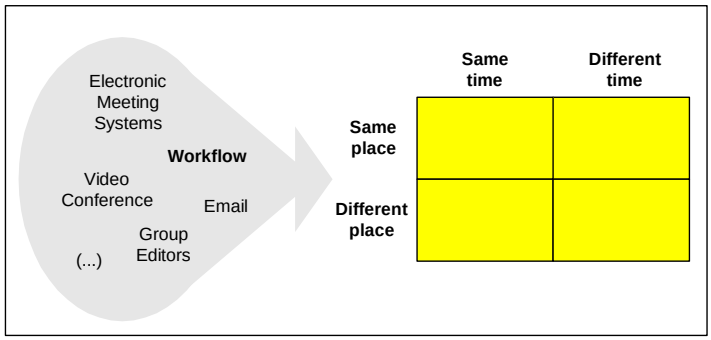

Fig. 2: Groupware technologies and the Johansen's Time/Space Matrix

Although workflow systems are normally viewed as a kind of groupware system, there is a subtle but significant difference between workflow and the other types of groupware. While all of them intend to facilitate the communication and collaboration among people, the workflow systems aim, more specifically, to coordinate their interactions according to a particular organisational process (Van der Aalst and Van Hee, 2004).

Among other authors, Davenport has defined the concept of organisational process as "*a specific ordering of work activities across time and place, with a beginning, an end, and clearly identified inputs and outputs: a structure for action*" (Davenport, 93). As an enabling technology, the fundamental idea behind workflow is the combination of individual tasks into a sequence of actions that achieve a goal, thus supporting directly the concept of organisational process. Consequently, the explicit support of organisational processes is the differentiating characteristic between workflow and the other groupware technologies.

The Workflow Management Coalition (WfMC), a non-profit international body created for the development and promotion of workflow standards, defines workflow as "*The automation of a business process, in whole or part, during which documents, information or tasks are passed from one participant to another for action, according to a set of procedural rules*" (WfMC, 1999). Therefore, the notion of process automation is central to workflow technology.

A widely accepted classification of workflow products distinguishes among four categories: ad-hoc, collaborative, administrative and production workflow (Hollingsworth, 2004). The differences among them consist, very broadly speaking, in the more or less rigidity of the process enactment. Thus, in one extreme, we find production workflow, which aims to support the enactment of completely pre-defined processes, executing them in a very rigid and strict way. Obviously, these workflow systems are adequate to support mission-critical business processes, where nothing can fail and everything must be executed according to the pre-defined process models. In the other extreme, we find collaborative workflow, where the focus is not so much the process per si, but the sharing of information among the people (actors) involved in the process (Becker et al., 2002).

In Marshak's opinion (1997), "*although these categories are very useful and have helped customers get their minds around a very complex and diverse set of products (…) it is important to remember that processes often span categories of applications.*" And she adds, "*a continuum is a better metaphor for viewing workflow categories.*" (Fig. 3).

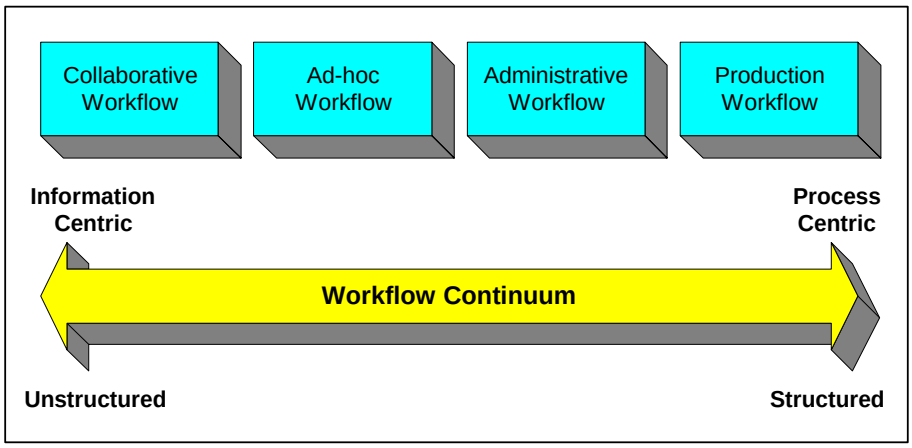

Fig. 3: The Workflow Continuum

Structured and ill-structured processes coexist in any organisation. In real work environments there are no completely structured processes. The most common situation is a mixture of structured and ill-structured parts in the same process specification.

Business Process Management Systems (BPMS) are the modern software systems that implement the workflow concept by managing the execution of business processes, according to their specification models. During the execution of a business process, the BPMS delivers work to actors (humans or machines) according to the correspondent process model and the execution context of each particular process instance. In doing this, the workflow engine of the BPMS invokes the suitable available applications with the corresponding data involved, thus creating the adequate execution context for each process activity (Dumas et al., 2013).

The success of the business process paradigm has led to the development of many commercial BPMS. These include Oracle Business Process Management Suite, TIBCO ActiveMatrix, AuraPortal, Bizagi BPM Suite, and so on. In the open source community BPMS products like jBPM, Bonita BPM or Intalio are also very successful in the market.

One of the main characteristics of current BPMS lies in the implicit assumption that each activity is an individual activity. In other words, each activity is executed by a single actor (human or machine) during a time interval. Obviously, we can think of many situations in which two or more actors have to collaborate at the same time (being in the same or different places) in the execution of the same activity (e.g., a meeting to make a group decision). The general idea here is to relax the former constraint and be able to see an activity also as a group activity (Fig. 4).

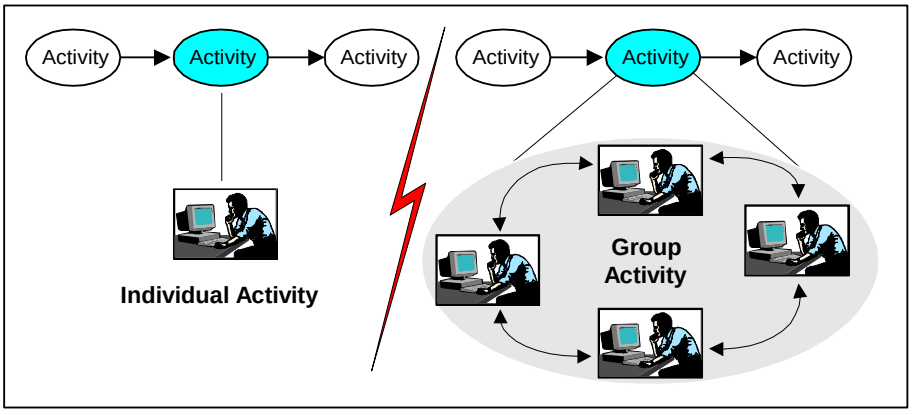

Fig. 4: Individual Activities vs Group Activities

In fact, groupware technology may be regarded by the BPMS in the very same way as the other more conventional information technologies. Clearly, the ideal environment to support the enactment of organisational processes will be made of BPMS flexible enough to support all kinds of processes (the workflow continuum), and transparently integrated with both groupware technology for the support of group activities, and the more conventional information technologies which typically support individual activities.

4. Towards Process-based Information Systems

The integration of the large number of independent and disconnected computer-based information systems, which usually exist in a typical organisation, has always been considered a critical issue. Indeed, this integration is a way to create a global vision of the information and processing resources of the organisation, allowing their joint management.

The first systems integration efforts began with the Data Base Management Systems (DBMS). The general idea consisted in defining a common data model to harmonise and integrate all the organisational information resources in a unique data repository, available to all information systems – the *corporate data model*. In addition, since the construction of a centralised repository containing all the organisational data was not always possible or even viable, other solutions were built, such as distributed data bases in which the data was physically dispersed in several repositories but was seen by the application level as a unique, logically integrated, repository.

This kind of systems integration may be called *integration-via-data* (i.e., the systems are interconnected via data repositories). Nowadays, owing to the facilities provided by the new groupware technologies and, in particular workflow technology, a new possibility of systems integration has emerged, much more ambitious and promising than integration-via-data: the *integration-via-processes*. Moreover, this kind of information systems integration directly matches with the new organisational paradigm (Pereira, 2014).

In the heart of the integration-via-processes approach are the modern BPMS. In fact, a BPMS may be regarded as a very sophisticated form of middleware which, more than allowing a passive interconnection between different systems, allows their *active interconnection*, making them cooperate explicitly in the execution of an organisational process. Thus, a BPMS may be seen as a coordination level, which, if placed over the information and collaboration systems of the organisation, is able to control their cooperation (Pereira, 2014). To this global solution we call *Process-Based Information System* (PBIS) (Fig. 5).

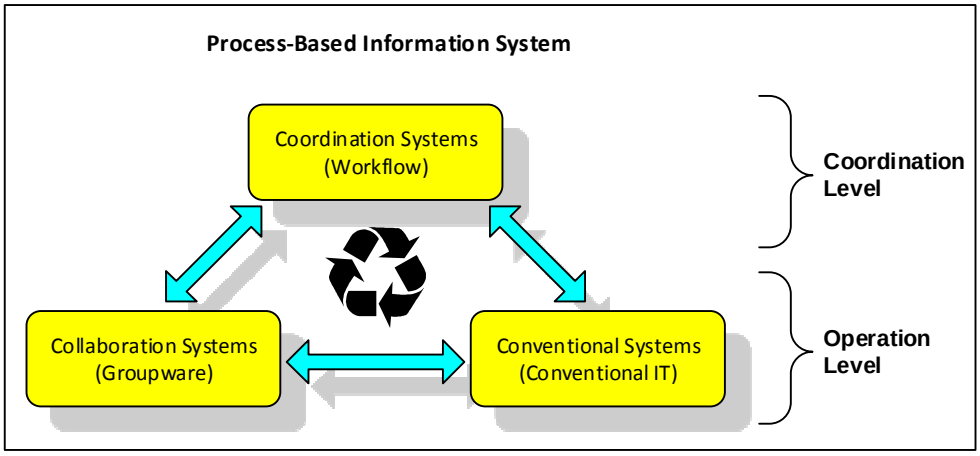

Fig. 5: Process-Based Information System components

Due to the fundamental characteristic of BPMS that allows the explicit separation of the process logic from the applications which implement the activities in the process model, it is possible to change or redefine the organisational processes (*coordination level*) without affecting the existing applications (*operation level*). Thus, BPIS stand highly configurable, maintainable, and flexible (Fig. 6).

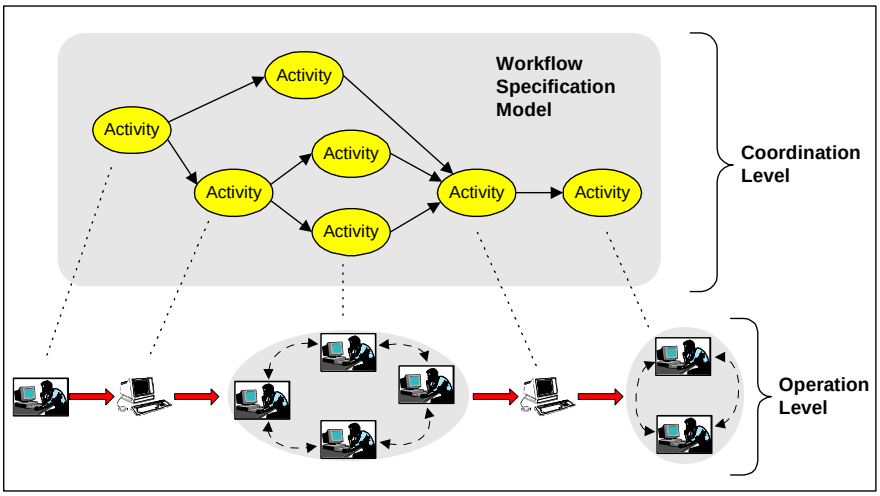

Fig. 6: The BPIS framework

This approach promotes the incremental development of Information Systems. In fact, the BPIS is developed piece by piece, in a very modular way, by adding successive process models to the coordination level, and reusing or, if not available in-house, developing or acquiring new applications in the operation level. As time goes by, the level of application's reuse will increase and, in the limit, the coordination level will be a fair representation of the *corporate process model*.

This ISD approach might also be regarded as a kind of component-based ISD, by analogy with component-based software development in the software engineering domain. A kind of "*programming in the large*", where complete software components, corresponding to autonomous applications, are combined and put to work together according to some organisational process specification. Furthermore, this architecture promotes the reutilization of those large software components by reusing them in several processes (Pereira, 2014).

Obviously, this is a framework which directly supports the new organisational paradigm (process-based organisations, teamwork and people empowerment), making use of the new technological infrastructure, and allowing organisations to develop and maintain their information systems quickly and easily (Pereira, 2014).

Clearly, the ideal environment to support the enactment of organisational processes will be made of BPMS flexible enough to support all kinds of processes (the workflow continuum), and transparently integrated with both groupware technology for the support of group activities, and the more conventional information technologies which typically support individual activities.

5. Requirements of a Methodology for Process-based Information Systems

If a BPMS is simply used to automate the routing of electronic documents between workstations, then the process models developed with the graphic editors normally provided by the BPMS are, in principle, sufficient. However, if one wants BPMS to behave like a coordination system that interconnects pro-actively several people and/or computer-based systems, according to a set of organisational processes, then a systematic approach to the development of this kind of systems, with an appropriate life cycle, must be used (Pereira, 2004). In other words, a PBIS development (PBISD) methodology is needed.

Now, the obvious question is: "What are the specific characteristics of PBIS which distinguish them from the more conventional information systems?" The immediate answer is that, PBIS, besides conventional information systems, implies also the existence of coordination and collaboration systems (see Fig. 5). Therefore, fundamental concepts such as organisational process and teamwork are now present.

In a very simplistic way, we can say that conventional information systems are developed with a simple goal in mind: the automation of a set of processing tasks over some kind of data repository.

When developing such a system, the critical issues are the identification of "*what needs to be done and how*" and "*which data is involved*". Thus, conventional information systems assume a task-oriented and data-oriented perspective.

Clearly, any approach to the development of PBIS must involve a joint analysis of the organisational processes (including their social and organisational issues), the applications required by the various activities that make up the processes, and the data processed by those activities.

Perhaps, the best way to characterise the scope of a PBISD methodology is to define the set of perspectives that must be considered when developing a PBIS. Besides the functional and informational perspectives of conventional information systems, we must analyse the coordination and collaboration dimensions of a PBIS.

Regarding the coordination dimension, Curtis et al. (1992) state that there are four critical perspectives in a process model:

- The functional perspective (*what needs to be done and how*)
- The informational perspective (*which data is involved*)
- The behavioural perspective (*when it is done*)
- The organisational perspective (*who does it*)

So, besides the functional and informational perspectives which are common to conventional information systems, at least two new perspectives (the behavioural and the organisational), with their corresponding modelling methods, must be considered in a PBISD methodology.

Concerning the collaboration dimension of PBIS we argue that the following three perspectives are essential:

- The group perspective (*who interacts with whom*)
- The interaction perspective (*what facilities are needed for the interaction*)
- The responsibility perspective (*who is responsible for the interaction*)

With these three additional perspectives, now we have, at least, seven perspectives we must consider in a PBISD methodology.

Business process models are the starting point for requirements specification of the systems to be developed. In this perspective, we assume that most of the issues and details that are needed to develop BPIS may be derived from business process models (see Fig. 7).

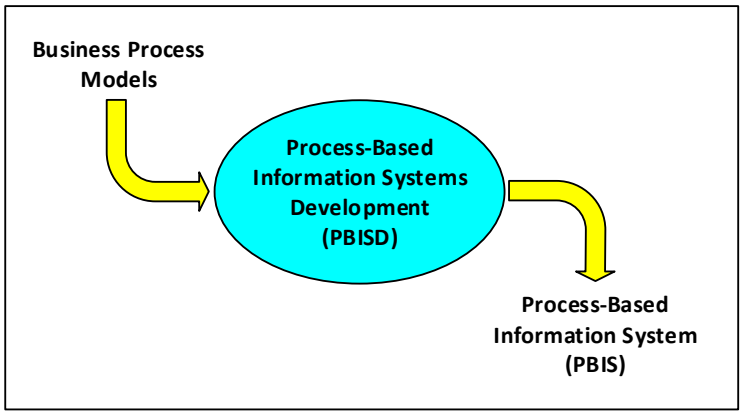

Fig. 7: From Business Process Models to BPIS

None of the conventional ISD methodologies takes into account all of these perspectives. In fact, the coordination and collaboration dimensions, critical in the development of PBIS, are simply not

considered in the conventional ISD methodologies that we are aware of. Therefore, it is our claim that a new PBISD methodology, that considers all the above perspectives, is needed.

6. Conclusion

Considering the functionalities made available by collaborative technologies, most particularly the workflow technology, it is now possible to evolve onto the integrated PBIS. Although there are today many information systems development methodologies, none of them takes into account the new technological developments, with characteristics radically different from the more conventional technologies, for whom those methodologies were made. Therefore, we need a new approach to information systems development that takes into consideration not only the more conventional technologies, but also the more recent collaborative technologies. In this paper, additionally to the definition of the PBIS concept, we have described the major requirements that a PBIS development methodology (PBISD) has to take into account.

Abstract

Over the last decade, digital data has known an incredible growth. Several businesses have taken advantage of this data abundance, and have moved their decision making strategy from hypothesis driven to data driven approaches. Therefore, new solutions are needed to store and access this big data, then infer knowledge out of it and make it available to managers.
In this paper, we will discuss briefly the different issues that should be taken into consideration for implementing a Big Data framework in companies. Then a solution implementation for a Middle East gas and oil distribution company will be presented.

Keywords: Big Data, Hadoop, MapReduce

Introduction

Nowadays, the progressive digitization of every aspect of everyday life has led to a never seen data explosion, called BigData. The business world is of no exception, and the digitization of every single operation or activity is becoming a standard. This collected data represents an unprecedented opportunity for decision makers but also a real challenge. Actually, data-driven decisions are better decisions since they are based on evidence rather than intuition. Therefore, efficient analysis and interpretation of this BigData opens new avenues to explore, new questions to ask, and new ways to answer the open issues. Such analyses lead to better understand the business and develop better and personalized solutions. However, such huge and heterogeneous amount of digital information need new and improved technological paradigms to deal with them. Storage, access, and mining of Bigdata to infer knowledge and to make it available to managers are some of the issues that should be covered.

There are several examples of big data use cases in virtually every industry. Some businesses have been more receptive of the technologies and faster to integrate big data analytics into their everyday business than others. Some examples of solutions include:
• Financial services providers adopt big data analytics infrastructure to improve their analysis of customers to help determine eligibility for equity capital, insurance, mortgage, or credit.
• Airlines and trucking companies use big data to track fuel consumption and traffic patterns across their fleets in real time to improve efficiencies and save costs.
• Healthcare providers manage and share patient electronic health records from multiple sources—imagery, treatments, and demographics—and across multiple practitioners. In addition, pharmaceutical companies and regulatory agencies create big data solutions to track drug efficacy and provide more efficient and shorter drug development processes.
• Telecommunications and utilities use big data solutions to analyze user behaviors and demand patterns for a better and more efficient power grid. They are also storing and analyzing environmental sensor data to provide insight into infrastructure weaknesses and provide better risk management intelligence.
• Media and entertainment companies use big data infrastructure to assist with decision making around customer lifecycle retention and predictive analysis of their user base, and to provide more focused marketing and customer analytics.

Big Data phenomenon has crippled the capabilities of modern IT infrastructures. Big data systems are now expected to model vast amounts of heterogeneous and complex data. Classical approaches of Data Base Management Systems (DBMS), Data Warehousing and Data Analysis are no longer viable to deal with both the scale of data and the sophisticated analysis that need to be conducted often in

real time. None of the commercial DBMS and Data Warehousing technologies provide an adequate solution in this regard. Therefore, P. Pääkkönen and D. Pakkala (2015) stated that through the recent technological advances in communication and computer science fields that have provided cost-effective solutions to acquire, transfer and analyze large amount of data, several promising tools have been developed to fill in this technological gap and handle the Big Data projects needs.

The first organizations to use Big Data techniques were information technology (IT) companies like Google, which created most of the software infrastructure needed to manage data in a scalable manner. Actually, several businesses have adopted a wide variety of Big data technologies and heterogeneous architectures that have resulted in major disruptions and transformations in their information technology infrastructures. Therefore, there is no standard BigData framework that is applicable to all businesses, but rather, several ones exist and vary a lot from field to field.

In this paper, a big data case study implementation will be discussed. It concerns the realization of a big data solution in a Middle East gas and oil distribution company. First, the company need for migration to a big data solution is presented. Then implementation issues and analytics findings are discussed.

A Big Data Use Case Implementation

A gas and oil distribution company's information system manages all the data from its different subsidiaries. Data comes from business applications, transactions, mobile application or GPS sensors. S. Chaudhuri and al. (2011) mentioned that With the exponential growth of data volume and the emergence of new sources, extraction, transformation and loading ETL have become more difficult and take more time.

Actually, the existing group's Business Intelligence (BI) Platform, based on the ETL, extract data from production systems, load them in the data warehouse, and then make the necessary changes in the staging tables using the data warehouse resources. However, with the big masses of accumulated data, these staging tables quickly become large and require more storage capacity which means an increasing high cost of data warehousing.

Two immediate problems have been identified: (i) an increasingly slow ETL treatment and dashboards loading, and (ii) an increasingly high storage costs. Therefore, two main issues will be addressed. The first issue concerns winning in performance. Actually, the objective is to optimize the decision-making chain, for loading, processing and data restitution, while taking into account the rapid growing volume of data. The second issue directly involves the solution's end users. It must correctly respond to their needs by offering relevant ergonomically arranged key performance indicators, displayed in dashboards that highlight the required information.

According to the above, the loading, processing and retrieval of data carried out through the existing BI platform have fairly a long execution time. This is due firstly to the complexity of the source databases which largely defines the architecture complexity of ETL jobs to be done, and secondly to the constantly growing data volume included in these databases and ETL on which treatments will be performed.

As an alternative to this latency problem, and in a view to improve the existing BI platform, Hadoop (Apache Hadoop, 2016) provides an architecture that enables both the storage and processing of the distributed data. Indeed, the data stored in HDFS (Apache Hadoop, 2016) are separated in different data blocks spread over all cluster machines. On the other hand, the different treatments carried out on the data are converted into MapReduce (M. Mavani, L. Ragha, 2013) jobs which allow, therefore, having the operations conducted in parallel on different machines in the cluster where there is gain in performance and treatment time. In this way, Hadoop takes advantage of all the available resources both in terms of storage capacity and execution time. However, Hadoop will not be a replacement of the BI platform already in place but rather a complement to face the limits of the latter, and taking advantage of what the Big Data technologies can offer.

To produce the needed dashboards, data has been extracted from the company's production databases to Hadoop HDFS and specifically Apache Hive [3]. These extracted data is the basis for the creation of aggregate tables that contain the essential measures for the development of dashboards. These aggregate tables were created using Hive Query Language namely HiveQL (Hive Query Language), then dashboards data was restored using QlikView (QlikView, 2016) tool. Cloudera Manager was used for monitoring the cluster to assess its condition. While Hue serve as a graphic web interface for all services used.

The data loading and creation of aggregate tables was included in a workflow managed by the oozie (Apache Oozie, 2016) service.

Conclusion

There are many open issues for Big Data management and analysis in the business world. In this paper, a Big Data solution implementation for a gas and oil distribution company has been discussed. The usage of Big Data Hadoop platform helped improve the performance at the data processing level through its distributed architecture.

As a perspective, it is possible to integrate Hadoop platform with the existing BI platform by translating the heavy ETL to MapReduce jobs, and exporting data warehouse dormant data to HDFS.

Abstract

The paper describes the methodological aspect of constructing index schemes by the Varzar ideology for two and three-factor multipliers. The index method is widely used by industry analysts; the price indices group is traditionally used for measuring the dynamics of the physical volumes of industrial output, the dynamics of wholesale, retail, purchasing and other prices and tariffs, calculation of the inflation rate, and the method is well-developed theoretically, all of which allows, in the authors' view, to measure the structural component of the inflationary spiral. This article demonstrates a method of assessing the effect of the costs inflation which forms the above-mentioned structural component, using as an example a machine-building company. The authors present graphic illustrations of the planar and the spatial procedures for factor increment analysis. These procedures are accompanied by an extended commentary on the results of an analytical expansion of the production output costs related to its structure, unit costs and prices for the raw materials used.

Keywords: process of inflation, inflation generated in industries, index-number method, analytical index, two- and three-factors multiplicative models, scheme of the factor's expand, graphic interpretation, the index of the joint changes (IJC), cost-push inflation

If you think that someone allows himself
too much, maybe you just largely deny yourself.
From A. Finagle's collection of folk wisdom

Historians of science have long noticed that there is an isomorphism between quantum physics and mathematical economics, which is based on their common relationship with mathematical statistics. Matching the calculated various indicators and indexes becomes particularly relevant at the present time in statistical methodology to assess the development of industrial sectors of the national economy. Special place in this methodology is occupied by the group of factor analytic indexes that measure the price dynamics, inflation, mobility, structural changes and other statistical aspects of economic processes.

As you know, the nature of tasks, composite indexes are divided into simple and analytical. Simple index assesses the quantitative change in one or another of the studied primary or secondary symptom as separate from other related features, and these are analyzed, they are indexed, the signs are considered in the analysis taken into account as the traits-factors, but aggregated for each of the covered periods.

Analytical index measures the change of resultant, which occurred due to the change of one of the considered characteristics on the factors included in the analytical unit of the index. In this way the analytical index is based on statistical concepts of rigidly deterministic relations. Change or influence of others, taken into account in the analysis of index signs-factors, in this case, is repaid, eliminated or eliminated by the fact that their level is fixed, or is fixed at a certain, predetermined period.

For example, consider the simplest two-factor multiplier that connects as direct characteristics of a

statistical connection, the size of the turnover by the j-th commodity item $W^{(j)}$ in the overall diversity of the product range $j = \overline{1,m}$, the physical volume of sales (bulk commodities in real terms) and the sales price per unit $p^{(j)}$. Their relationship is defined in the so-called reporting and reference periods by the following multipliers

$$W_1^{(j)} = Q_1^{(j)} p_1^{(j)}; \qquad W_0^{(j)} = Q_0^{(j)} p_0^{(j)}. \tag{1}$$

While no theoretical or technical problems arise in respect of holding of the index analysis of resultant $W^{(j)}$, related to factor analysis the right part of the multiplier of two signs of the causal factors of the expressions (1) this cannot be stated with confidence, even in such a trivial case as k = 2 (the number of independent traits-factors).

In the statistical theory of index method there are two approaches to the solution of this difficult question. The first approach (regulated) binds a variety of period scales with the character and nature of indexed values. Namely: if the unit is indexed/analyzed the so-called initial symptom, the corresponding "weights" are fixed at the level of the base period; if indexed/analyzed secondary symptom, then its weighting is carried out on a reported basis weight characteristics.

This analytical index provides a very satisfactory correlation indices of resultant signs and factors, ensures their circular reducibility in relative and absolute terms numerically evaluated factorial increments. The procedure considered for constructing the analytical factor indexes historically has generated the widely known, quite versatile and relatively powerful method of economic analysis which is the method of chain substitutions, using such a method of forming direct statistical characteristics of the relationships between signs within the so-called index I and II systems. The analyzed relationship is realized through canonical and understandable expression (2) in general, the considered product portfolio of m positions

$$\Im_{W(Q,p)1/0} = \Im_{W(Q)1/0} \times \Im_{W(p)1/0} = \frac{\sum_{j=1}^{m} Q_1^{(j)} p_0^{(j)}}{\sum_{j=1}^{m} Q_0^{(j)} p_0^{(j)}} \times \frac{\sum_{j=1}^{m} p_1^{(j)} Q_1^{(j)}}{\sum_{j=1}^{m} p_0^{(j)} Q_1^{(j)}} = \frac{\sum_{j=1}^{m} Q_1^{(j)} p_1^{(j)}}{\sum_{j=1}^{m} Q_0^{(j)} p_0^{(j)}} = \frac{\sum_{j=1}^{m} W_1^{(j)}}{\sum_{j=1}^{m} W_0^{(j)}}. \tag{2}$$

The first approach has its advantages and disadvantages, the detail considered by such researchers as Kaufman A. A., and Kazinets L. S., Rothstein A. I. Ploshko B. G., Tornkvist L., Frenkel A. A., Edelhaus G. E., Edgeworth F., Marshall A. and others. Shortcomings inherent in this approach were resolved in 1933 by the compound average geometric index of I. Fisher that the author called modest and unpretentious, «perfect». But the procedure for determining the period of the scales is generally accepted in Russian and international official statistics in economic and operational analysis, although the actual shortcomings of the approach are rather obvious. So, fixing the weights in indexes of secondary signs, constructed according to the regulations, at the level of the reporting period, artificially created obstacles to the objective evaluation of a stand-alone account of the influence of each of the recorded of the traits-factors.

For example, when analyzing the change of the price factor in the dynamics of $p_0^{(j)} \Rightarrow p_1^{(j)}$ the index that is built on reporting weight characteristics, in addition to taking into account changing the actual indexed values also influence by changing the reporting period and the status of the attribute-weight $Q_1^{(j)}$, i.e., its structural and quantitative certainty, but the subsequent period of the dynamics.

This may simplistically be considered the main drawback of the classic scheme of the index analysis.

The second approach to the definition of the weights in the analytical indexes involves the construction of any and all related indexes on the scales of exclusively the base period. Let us note that the permissible analyst position fully meets the goals and objectives of any research, i.e. to obtain the most accurate assessment of isolated effects (actions) of each of the recorded signs of causal factors on the productive trait-factor, provided that the circular reducibility index obtained for all characteristics will be met. Respectively, all of the signs of the factors taken into account are analyzed in turn by the index in a sequence specified in any way and, of course, justified in terms of content and subject to the requirements of consistency.

It is interesting to note the use of both approaches to the construction of the classical indexes of Paasche prices (Paasche price index – P), proposed in 1874 and Laspeyres (Laspeyres price index – L), introduced into scientific circulation even earlier, in 1864. Both the price indexes in statistical practice are even used simultaneously to measure the cost of living, i.e., incurred costs for the maintenance of living standards in the ideal index1. The canonical form of these indices are shown in expressions (3)

$$\Im_{p_{1/0}}^{(P)} = \frac{\sum_{j=1}^{m} p_1^{(j)} Q_1^{(j)}}{\sum_{j=1}^{m} p_0^{(j)} Q_1^{(j)}}; \qquad \Im_{p_{1/0}}^{(L)} = \frac{\sum_{j=1}^{m} p_1^{(j)} Q_0^{(j)}}{\sum_{j=1}^{m} p_0^{(j)} Q_0^{(j)}}. \tag{3}$$

The Paasche price indices, i.e., with weights of the reporting period, are calculated on a wider range of goods, works and services. Due to the fact that the weights of these indexes is not the structure of consumer spending, and the structure of turnover or gross value added, or production in the current period, they (weight) can be determined only at the end of the reporting period. Therefore, the Paasche index takes into account the results of mutual replacement of products, but does not reflect what is happening at the same time reducing the level of welfare of the population.

The index $\Im_{p_{1/0}}^{(P)}$ is used in the measurement of the dynamics of prices of components of GDP, input prices in agriculture, estimated construction prices, export prices, etc. According to the algorithm of the Paasche index such an important macroeconomic indicator as the deflator of the gross domestic product index deflator or the GDP-deflator (Gross Domestic Product deflator), reflecting the ratio of the nominal GDP to real GDP, is also calculated.

A. Gerschenkron, an American researcger (of Russian origin), used both indices in the formulas from (3) in the mid-twentieth century to construct his own index, with which he studied the specific effects (effect of Gerschenkron) in Soviet and American economies and thereby made a significant contribution to the analysis of inflationary and structural processes. The index feature is often called the analytic index of prices by Gerschenkron ($\Im_{p_{1|/0}}^{(G)}$) in contrast to the price indexes of Paasche and Laspeyres, and it has the following type and value:

$$\Im_{p1/0}^{(G)} = \Im_{p1/0}^{(L)} : \Im_{p1/0}^{(P)} = \frac{\sum_{j=1}^{m} p_1^{(j)} Q_0^{(j)}}{\sum_{j=1}^{m} p_0^{(j)} Q_0^{(j)}} : \frac{\sum_{j=1}^{m} p_1^{(j)} Q_1^{(j)}}{\sum_{j=1}^{m} p_0^{(j)} Q_1^{(j)}} > 1.$$

(4)

[1] Index of I. Fisher in the presented expressions has a traditional look $\Im_{p1/0}^{(F)} = \sqrt{\Im_{p1/0}^{(L)} \times \Im_{p1/0}^{(P)}}$.

The systematic lagging of $\Im_{p1/0}^{(P)}$ behind $\Im_{p1/0}^{(L)}$, fixed in the expression (4), allowed the index to become the main inflation indicator. In connection with the detected circumstance, the Laspeyres index was named Index of consumer prices and tariffs of CPI (Consumer Price Index) 2. For price indices is due to the redistribution over time of demand with a relatively faster rising price of goods for goods, the relative prices of which are correspondingly reduced.

The index $\Im_{p1/0}^{(L)}$ does not take into account the possibility of replacing more expensive items less expensive. The CPI is one of the approaches to measuring shifts in prices of a market basket of constant set of goods and services. The CPI is a measure of the general price level, reflecting the change in the price of many consumer goods and services and represents the ratio of the prices of the consumer basket to its price in the base year. The composition of the consumption basket, as can be seen from this definition, is fixed at the base period.

Even more problematic is the interpretation of the so-called spatial Edgeworth-Marshall index, whose formula $\Im_{p1/0}^{(E-M)}$ is also able to capture the shifts in the structure of production and sales. However, the aggregate index is tied to the conditional structure of the scales, not typical for any of the real periods. Moreover, the index calculation meets known obstacles in collecting statistical information, and the interpretation of the direct economic sense are traditionally difficult.

The price indices calculated according to the Laspeyres formula are especially widely used in the calculation of producer price indices for industrial products according to the price of commodities-representatives (the so-called comparable range of elements). However, this index does not include investment goods, but this takes into account the price of imported products. Another use of the indicator $\Im_{p1/0}^{(L)}$ is its inclusion in the valuation model of inflation; thus, in the calculation of inflation for their own purposes Gazprombank uses so-called core consumer prices corrected for seasonality (BIPUS).

Inflationary processes in the economy are estimated typically using two indexes discussed above, and they are used in the compilation of data on aggregate units (e.g., enterprises, regions, countries) or to elements (for example, by type of goods) and units and elements. So, approved by Decree of Goskomstat of the Russian Federation "Position about the order of supervision over prices and tariffs for goods and services that determine consumer price index" indicates that the CPI is "one of the most important indicators characterizing the level of inflation, and is used to implement state financial policy, analysis and forecasting price developments in the economy, the regulation of the real rate of the national currency, the revision of minimum social guarantees, settlement of legal disputes".

Exact knowledge of the inflationary characteristics is extremely important for making sound political decisions, with serious social consequences. So the first half of 2015 representatives of the Ministry of Finance and Ministry of economic development proposed to index pensions in 2016-2018 only on the target level of inflation to about 4.0-5.5%. And this is assuming that in 2014, the official inflation rate was 11.4% and in 2015 it is planned already at 12.2%.

[2] The main purpose of the CPI is to estimate the dynamics of prices of consumer goods. The resolution of the International Labour Organization (ILO) stipulates that "the purpose of the calculation of the CPI is to assess changes over time in the General level of prices for goods and services acquired, used or paid by the population for unproductive consumption."

The CPI is calculated with weekly, monthly and quarterly periodicity and cumulatively for the period from the beginning of the year. The final values of the CPI for the month, quarter, year are determined before the 15th of the month following the reporting period. And one of the major problems concerning the content characteristics of the CPI, associated with the definition of methodological approaches to establishing the size and composition of the consumer basket. Determination of the size and range of composition of the consumer basket is not an easy task, which is based on special statistical studies, because the consumer basket should reflect the composition of consumption goods typical for the country, the change in the prices for which would objectively show the direction of the ongoing economic processes.

According to guidelines provided by Rosstat, CPI maintains information about the consumer price of 380 goods and services in 350 cities of the Russian Federation. The Russian variation of the CPI includes all major groups of goods and services, covering 400 thousand quotations of prices and tariffs, 30 thousand enterprises of retail trade and services. The set of goods and services studied for the calculation of the CPI includes goods and services to mass consumer demand, as well as individual goods and services non-essential items (cars, jewelry). In the analyzed composition of the consumer basket 26.2% are food products, 52.6% – non-food products and 21.2% — paid services.

The structure of consumer expenses of the population for the previous year is used as weights for the current year. The CPI is calculated by using weights of the previous year, which each year are updated. The main source of obtaining the weights is the annual survey of households ' budgets. The sample of households for examination of their budgets is based on the principles of random selection. As a base for the construction of the sample the information array is used, created on the basis of materials of the micro-census of the population of 2012 in the Russian Federation. The volume of sample at 48.7 thousand households, i.e. about 0.1% of the total number of households in the Russian Federation.

In the USA, the calculation of the CPI statistics covers more than 19 thousand retailers and 57 thousand households as a representative sample of approximately 80% of the population. In the composition of the consumer basket there is 44.1% commodities and 55.9 per cent service. Considering the representativeness of the sample survey, covering goods and services of the constant demand (food, clothing, fuel, transportation, medical care, etc.), we should agree with the opinion of the analysts of statistical agencies, as the Russian Federation and other countries, particularly the USA (Bureau of labor statistics) the CPI can indeed be considered as the main indicator of inflation. But the specifics of the moment of the crisis in the state of the national economy, particularly beginning in 2015, is that the decline in production dictated the need to pay close attention to the measurement of inflation of different types – cost-push inflation.

In a market economy cost-push inflation is due to short-term excess of aggregate supply over aggregate demand due to a sharp increase in the prices of factors of production. This increase, as a rule, is caused by either lean years and a significant rise in export of raw materials, or deep devaluation of the national currency. Even in a quasi-market economy such a process is accompanied by a decline in production and rising unemployment3. With unchanged aggregate demand, this may cause a cost reduction of wages and reduction of other costs of the factors of production that, ultimately, should lead to lower prices.

If this situation is increasing the money supply and nominal federal spending, aggregate demand increases, output increases, unemployment reduces, but there is a further growth of prices for final products along the value chain. Such kind of inflation, as treated by the economic theory, is produced also in the cases when the basic sectors of the economy (with the specificity of commodity economy), often coinciding with areas of activity of natural monopolies, no longer function according to market laws and fall under government control and regulation. Then these agents prescribe the growth of prices and tariffs for their economic benefits above market average growth in prices.

[3] In the Russian Federation, the unemployment rate fast approaching 6.5 per cent of the economically active population.

Inflation analysts notice that in crisis conditions the growth rate of monetary inflation substantially exceed the growth rate of structural inflation. Core inflation does not include seasonal and administrative effects on prices. Structural inflation, as expected, reflects structural shifts in production and leading to higher prices mainly in industries where product demand is outpacing product offering.

Analysts believe the weakening of the ruble to be a major factor in the increase in inflation, because its impairment, apart from the obvious fact – the rising cost of imports, stimulates the acceleration of turnover of cash. The latter in itself can have inflationary consequences. Additional factor of increase in monetary inflation can be the the propensity to consume growing in the unstable economy, as the authors say in the paper. Upward momentum of this tendency, sometimes in the mode of excessive demand, is fueled by distrust of legal and natural persons to an unstable banking system and marked inflationary expectations.

Returning to the index $\mathfrak{I}_{p1/0}^{(G)}$, note that Gerschenkron's effect is manifested not only in the analysis of prices and tariffs, but also in the analysis of quantities, i.e., physical volume, or mass of commodities, and is also found in the studies a mandatory component of the time trend study indices of industrial production (volume indices), which are regularly calculated on a monthly basis by the Center of economic conjuncture under the Government of the Russian Federation. Using only the base weights eliminates the main observed drawback of the first approach. However, another problem arises instead – ensuring the alignment between analytical indexes, let's call them "basic indices" in any meaningful system. Pure factor indices built in this system with the index not form an effective feature. We illustrate this difficulty with the example of the mentioned turnover by this ratio

$$\mathfrak{I}_{W(Q)1/0} \times \mathfrak{I}_{W(p)1/0} \neq \mathfrak{I}_{W(Q,p)_{1/0}}. \quad (5)$$

~~$Q_0 \to Q_1$~~	~~$Q_0 = const$~~	~~$Q_0 \to Q_1$~~
$p_0 = const$	$p_0 \to p_1$	$p_0 \to p_1$

A convincing explanation of this seemingly natural result arising from the expression (5), are the following considerations: the isolated assessment of the changes of individual factors does not take into account the fact that actual changes $(Q_0^{(j)} \Rightarrow Q_1^{(j)}; p_0^{(j)} \Rightarrow p_1^{(j)})$ occur in the real economic environment, in particular trade and commercial operations and are implemented not only jointly but are also interdependent. This circumstance determines the particular statistical effect, complementing the effects of isolated changes in individual factors. The necessity of considering such a joint change of the factors in the theory of economic analysis is obvious. The effect is measured according to the scheme of V. Varzar4 known as an Index of joint changes (JCI) with its different variants used in different analytical tasks.

Consider a planar illustration of the diagram, or the "sign of Versar" in the case of turnover, i.e., with respect to the two-factor multiplier from the expression (1). The chart presented on the plane is focused on the two-factor multiplicative model. Basis and reporting the status value of the turnover of the j-th commodity goods coincide in sense with the areas of rectangles with relevant stakeholders $\{Q_0^{(j)}, p_0^{(j)}\}$ and $\{Q_1^{(j)}, p_1^{(j)}\}$. The transition of trade from the basic state $W(Q_0^{(j)}, p_0^{(j)})$ in the reporting $W(Q_1^{(j)}, p_1^{(j)})$ geometrically indicates a change of source area (rectangle 1) by adding three additional areas, as shown in Fig. 1.

[4] Varzar (Varzer) Vasily Egorovich (1851-1940) — Russian, Soviet statistician and economist, academician, founder of industrial statistics in Russia. Organized two of the first major statistical survey (census)

$$W(Q_1^{(j)}, p_1^{(j)}) = W(Q_0^{(j)}, p_0^{(j)}) + W(\Delta Q_{1/0}^{(j)}, p_0^{(j)}) + W(\Delta p_{1/0}^{(j)}, Q_0^{(j)}) + W(\Delta Q_{1/0}^{(j)}, \Delta p_{1/0}^{(j)}).$$

(6)

In order to find the absolute increment in the volume of trade turnover in the reporting period compared with the baseline, we must reference the feature $W(Q_0^{(j)}, p_0^{(j)})$ to move to the left side of the expression (6), respectively, with the opposite sign

$$\Delta W(Q^{(j)}, p^{(j)})_{1/0} = W(Q_1^{(j)}, p_1^{(j)}) - W(Q_0^{(j)}, p_0^{(j)}) = W(\Delta Q_{1/0}^{(j)}, p_0^{(j)}) +$$
$$+ W(\Delta p_{1/0}^{(j)}, Q_0^{(j)}) + W(\Delta Q_{1/0}^{(j)}, \Delta p_{1/0}^{(j)}).$$

(7)

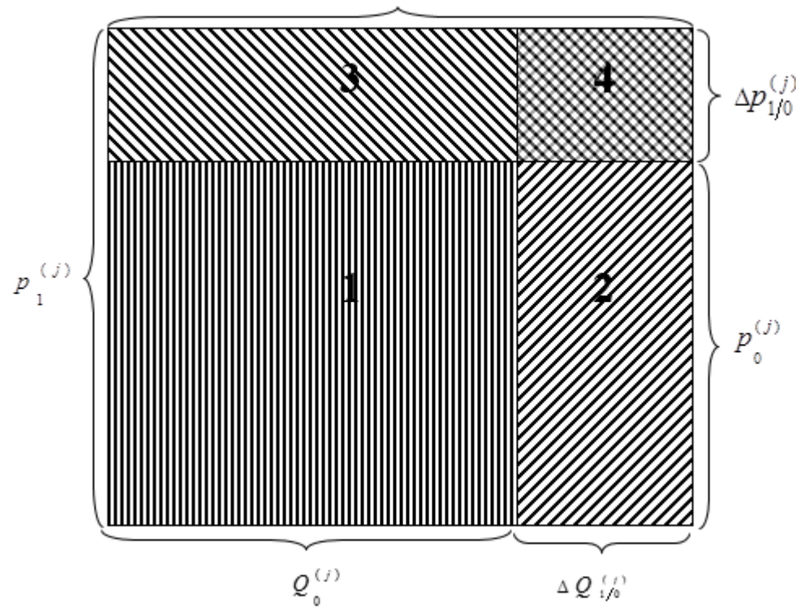

Fig. 1: A graphical representation of the index joint changes (IJC) V. Varzar

1 – original volume value of the turnover of the base period (last year); 2 – the change in the value due to the growth of commodity mass in the reporting period (the current year); 3 – the change in the value due to the change of the price factor; 4 – the change in the value due to the simultaneous and combined changes and volume, and price.

The expression (7) represents the differential form of the appropriate and simple analytical indices (i.e. in absolute terms), each of which has its special purpose and meaning. When we switch to the traditional form of analytical indexes in relative terms, each of which corresponds to the differential forms of equation (7) as separate components, the so-called III index system is formed, which is focused on the evaluation of the phenomenon of joint changes (rectangle 4 in Fig. 1) that provides a measure of the effect of Varzar.

$$\Im_{W(Q,p)1/0} = \Im_{W(Q)1/0} \times \Im_{W(p)1/0} \times \Im_{W(\Delta Q_{1/0},\Delta p_{1/0})1/0} = \begin{matrix} \boxed{\begin{matrix} Q_0 \to Q_1 \\ p_0 \to p_1 \end{matrix}} & \boxed{\begin{matrix} Q_0 \to Q_1 \\ p_0 = const \end{matrix}} & \boxed{\begin{matrix} Q_0 = const \\ p_0 \to p_1 \end{matrix}} \end{matrix}$$

$$= \frac{\sum_{j=1}^{m} Q_1^{(j)} p_0^{(j)}}{\sum_{j=1}^{m} Q_0^{(j)} p_0^{(j)}} \times \frac{\sum_{j=1}^{m} p_1^{(j)} Q_0^{(j)}}{\sum_{j=1}^{m} p_0^{(j)} Q_0^{(j)}} \times \left[\frac{\sum_{j=1}^{m} p_1^{(j)} Q_1^{(j)}}{\sum_{j=1}^{m} p_0^{(j)} Q_1^{(j)}} : \frac{\sum_{j=1}^{m} p_1^{(j)} Q_0^{(j)}}{\sum_{j=1}^{m} p_0^{(j)} Q_0^{(j)}} \right]. \quad (8)$$

The entry components in the square brackets of the formula from expression (6) allows to obtain two significant modifications of the index joint changes $\Im_{W(\Delta Q_{1/0},\Delta p_{0_{1/0}})1/0}$. The first modification represents the actual index of Varzar ($\Im_{p1/0}^{(V)}$) in the form of the ratio, return the Gerschenkron index, i.e., quantitatively characterizing the opposite of a systematic lag of price index of Paasche (P) from the Laspeyres index (L).

$$1) \quad \frac{\sum_{j=1}^{m} p_1^{(j)} Q_1^{(j)}}{\sum_{j=1}^{m} p_0^{(j)} Q_1^{(j)}} : \frac{\sum_{j=1}^{m} p_1^{(j)} Q_0^{(j)}}{\sum_{j=1}^{m} p_0^{(j)} Q_0^{(j)}} = \Im_{p1/0}^{(V)}. \quad (9)$$

That is, the index of the joint changes from expression (9), as can be seen, is the ratio of the other two above-mentioned price indices with the corresponding value of the ratio:

$$\Im_{p1/0}^{(V)} = \Im_{p1/0}^{(P)} : \Im_{p1/0}^{(L)} < 1. \quad (10)$$

This analysis allows to assess the dynamics of changing prices in the calculation and reporting reference range produced and sold commodity mass, which is extremely important to detect the deterioration (or improvement) in the quality of consumption benefits paid and ultimately the quality of life. Note also the presence of inverse proportion of indices $\Im_{p1/0}^{(G)}$ and $\Im_{p1/0}^{(V)}$, which follows from expressions (4) and (10), which, however, does not stop to comment on the impact of structural changes in the product range on the level of prices and inflation expectations in any sequence.

Another modification of the joint of the index changes can be obtained based on expression (7) as the source by using the analytical reception of the so-called replacement of the elements of the secondary diagonal and the subsequent rearrangement of the factors in the numerators and the denominators are already the corresponding volume indices – $\Im_{Q(p_1)1/0}$ and $\Im_{Q(p_0)1/0}$.

$$2) \quad \frac{\sum_{j=1}^{m} p_1^{(j)} Q_1^{(j)}}{\sum_{j=1}^{m} p_0^{(j)} Q_1^{(j)}} \cdot \frac{\sum_{j=1}^{m} p_1^{(j)} Q_0^{(j)}}{\sum_{j=1}^{m} p_0^{(j)} Q_0^{(j)}} = \frac{\sum_{j=1}^{m} p_1^{(j)} Q_1^{(j)}}{\sum_{j=1}^{m} p_1^{(j)} Q_0^{(j)}} : \frac{\sum_{j=1}^{m} p_0^{(j)} Q_1^{(j)}}{\sum_{j=1}^{m} p_0^{(j)} Q_0^{(j)}} = \frac{\sum_{j=1}^{m} Q_1^{(j)} p_1^{(j)}}{\sum_{j=1}^{m} Q_0^{(j)} p_1^{(j)}} : \frac{\sum_{j=1}^{m} Q_1^{(j)} p_0^{(j)}}{\sum_{j=1}^{m} Q_0^{(j)} p_0^{(j)}} = \Im_{Q(p_1/p_0)1/0}. \quad (11)$$

During these elementary transformations two indexes of physical volume of commodity weight were obtained in the calculation for the reported and the basic level of pricing, which gives a second modification of the Varzar index of joint changes, more commonly known as the product range offset index (not to be confused with a second analytical index – the structure index, or index of structural

shift of the I Index system).

Both versions of the joint index of changes (the Varzar index $\Im_{p1|/0}^{(V)}$ and the product range offset index) capture from different positions of the joint price change and product supply at the trade which "with equal success and equally unreasonably" can be assigned to the first and second factors. Modifications convincingly demonstrate the diversity index measurements, the conventionality index of individual characteristics, objective limits of the scope and at the same time the specificity of application of each of them. The construction of the combined changes during the transition from planar images to three-dimensional image, i.e., carrying out similar procedures for three-factor multiplier causes even established researchers specific difficulties in terms of interpreting.

For example, for a model featuring a direct statistical correlation, the costs of raw materials in the process of manufacturing the j-th part – C(j), its dependences on the number of parts – Q(j); specific consumption of raw materials – s(j) and the unit prices of raw materials – p(j) throughout the nomenclature $j=\overline{1,m}$, respectively, in the reported and the base periods of operation of plant section of the engineering enterprise are reflected by the formulas from (12)

$$\sum_{j=1}^{m} C_0^{(j)} = \sum_{j=1}^{m} Q_0^{(j)} s_0^{(j)} p_0^{(j)}; \quad \sum_{j=1}^{m} C_1^{(j)} = \sum_{j=1}^{m} Q_1^{(j)} s_1^{(j)} p_1^{(j)} . \tag{12}$$

Any other combination of traits-factors is invalid, since only the given sequence can be yield economically meaningful and informative indicators: first, the physical volume of raw materials that went into the production of parts for j-th type – Q(j)×s(j), and then the cost of working capital in the amount of product – (Q(j)×s(j))×p(j). The structural transition from the baseline assessment (condition) of full costs for raw materials to actual costs of the reported period may be by analogy with the sequence of counting operations of Figure 1 shown in the diagram of the formation of a joint index of changes in three-dimensional space {Q, m, p} in Fig. 2.

Fig. 2 shows a visual 3d representation of the geometrically estimated areas of the conditional parallelepiped in the form of quantity of the used raw materials at the j-th product, based on which the volumetric parameters of signs, numerically coincident with the value – C(j) are calculated. In this case, a composite index of changes in costs in the reporting period (e.g. per day, week, month, quarter, etc.) as compared with the base within the III Index of the system (the basic indices) will have the following view containing a review of the framework under each of the analytical indices in the formulas from (13):

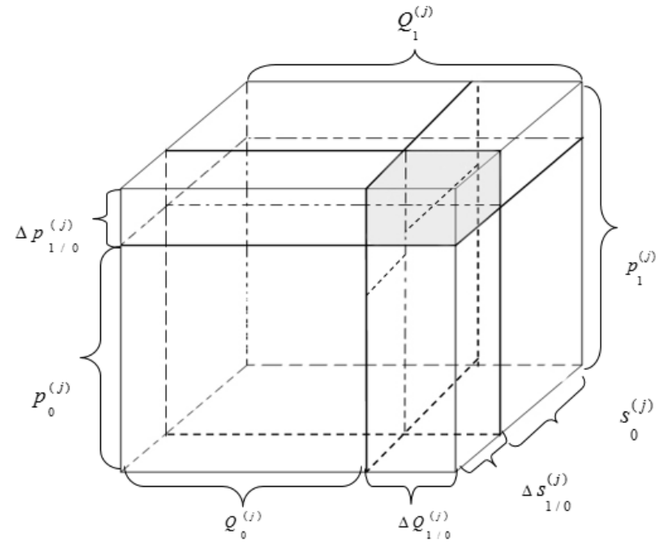

Fig. 2: The 3D-illustration of procedure of the index joint changes the cost consumed in the production process working capital in the space of variables {Q, s, p}

$$\mathfrak{I}_{C(Q,s,p)1/0} = \left|\begin{array}{c} Q_0 \Rightarrow Q_1 \\ s_0 \Rightarrow s_1 \\ p_0 \Rightarrow p_1 \end{array}\right| \times \left|\begin{array}{c} Q_0 \Rightarrow Q_1 \\ s_0 = const \\ p_0 = const \end{array}\right| \times \left|\begin{array}{c} Q_0 = const \\ s_0 \Rightarrow s_1 \\ p_0 = const \end{array}\right| \times \left|\begin{array}{c} Q_0 = const \\ s_0 = const \\ p_0 \Rightarrow p_1 \end{array}\right|_{1/0} =$$

$$= \frac{\sum_{j=1}^{m} Q_1^{(j)} s_0^{(j)} p_0^{(j)}}{\sum_{j=1}^{m} Q_0^{(j)} s_0^{(j)} p_0^{(j)}} \times \frac{\sum_{j=1}^{m} Q_0^{(j)} s_1^{(j)} p_0^{(j)}}{\sum_{j=1}^{m} Q_0^{(j)} s_0^{(j)} p_0^{(j)}} \times \frac{\sum_{j=1}^{m} Q_0^{(j)} s_0^{(j)} p_1^{(j)}}{\sum_{j=1}^{m} Q_0^{(j)} s_0^{(j)} p_0^{(j)}} \times$$

$$\times \left\{ \left[\frac{\sum_{j=1}^{m} Q_1^{(j)} s_1^{(j)} p_1^{(j)}}{\sum_{j=1}^{m} Q_1^{(j)} s_1^{(j)} p_0^{(j)}} \times \frac{\sum_{j=1}^{m} Q_1^{(j)} s_1^{(j)} p_0^{(j)}}{\sum_{j=1}^{m} Q_1^{(j)} s_0^{(j)} p_0^{(j)}} \right] : \left[\frac{\sum_{j=1}^{m} Q_0^{(j)} s_1^{(j)} p_0^{(j)}}{\sum_{j=1}^{m} Q_0^{(j)} s_0^{(j)} p_0^{(j)}} \times \frac{\sum_{j=1}^{m} Q_0^{(j)} s_0^{(j)} p_1^{(j)}}{\sum_{j=1}^{m} Q_0^{(j)} s_0^{(j)} p_0^{(j)}} \right] \right\}. \quad (13)$$

From the expression (11) it follows that the index of joint changes in the present embodiment represents the ratio of the number of indices of dynamics of prices and unit costs of raw materials, as constructed according to the Paasche scheme and Laspeyres scheme:

$$\mathfrak{I}_{C(\Delta Q,\Delta s,\Delta p)1/0} = \frac{\mathfrak{I}_{s1/0}^{(P)} \times \mathfrak{I}_{p1/0}^{(P)}}{\mathfrak{I}_{s1/0}^{(L)} \times \mathfrak{I}_{p1/0}^{(L)}}. \quad (14)$$

These very interesting and informative ratio of factor units from the expression (14) allow for the definition of the objectives of the study to create a rich set of index combinations of different

analytical focus and use them to conduct a comprehensive techno-economic analysis of the dynamics of primary and secondary signs of any depth and detail in the implementation of diagnostics of a condition of economic activity at the micro level of economic entities, the real sector of the economy at the meso- and macro- levels of regional and national economy.

We illustrate the considerations above by a conventional example, for which the data is presented in table. 1.

Table 1: The source data for the analysis by the index method of the three-factor multiplier measuring the material costs of a machine-building enterprise

№ p/p	Item name in the product range	The base period			The reported period		
		quantity, units	specific consump-tion, kg/unit	the price of raw materials, RUB/kg	quantity, units	specific consump-tion, kg/unit	the price of raw materials, RUB/kg
$j=\overline{1,m}$	j	$Q_0^{(j)}$	$s_0^{(j)}$	$p_0^{(j)}$	$Q_1^{(j)}$	$s_1^{(j)}$	$p_1^{(j)}$
1	2	3	4	5	6	7	8
1	Valve seat*	3 000	2,5	3 132	2 900	2,2	3 256
2	Roller assembly**	2 000	5,5	862	1 700	5,0	911

Notes to the table. 1:
* a product designed for the aviation industry, made of bronze Brazh GOST 613-79 of brand Brainz 10-3-1,5;
** a product for the machinery processing industry, made of chromium-Nickel pig iron with heat - and wear-resistance code "OKDP 11 271 27", brand ЧХ9Н5.

The results of performing the necessary analytical calculations for the traditional rules and scheme of Varzar are listed in the table of the summary characteristics – table. 2. The date of the 5th column from this table show a general decrease in the commercial mass of the producer (-6.69%), reflecting the overall crisis of the real economy, while the specific production causes inflation processes and the increase in costs due to the increase of prices amounted to 4.42%. This may lead to a false impression of the rationalization of production with general cost reductions at the enterprise for these types of products (-13.51%).

Table 2: Summary table of results of the influence of considered factors on the total material costs of production in traditional assessment, and by the Varzar scheme of (IJC)

No. factor p/p	Factor name	Symbols	Comparative level of cost changes by the method of chain substitutions				Ad valorem characteris-tics according to the scheme of Varzar, %	
			absolute deviation, RUB	analytic factor index, %	in % to the total deviation	in % to the cost of the base period	The Gerschenk ron factor indexes	in % to the cost of the base period
$k=\overline{1,K}$	$x^{(k)}$	$C(x^{(k)})_{1/0}$	$\Delta C(x^{(k)})_{1/0}$	$\mathfrak{I}_{C(x^{(k)})_{1/0}}$	$\frac{\Delta C(x^{(k)})_{1/0}}{\Delta C(Q,s,p)_{1/0}}$	$\frac{\Delta C(x^{(k)})_{1/0}}{C(Q,s,p)_0}$	$\mathfrak{I}^{(G)}_{x(k)_{1/0}}$	$\frac{\Delta C(x^{(k)})_{1/0}}{C(Q,s,p)_0}$
1	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**
	The change in the value of costs due to:							
1	the change in the	$C(Q)_{1/0}$	-2 205 300	93.31	49.50	-6.69	93.31	-6.69

	volume of products							
2	changes in unit cost of raw materials per unit of product	$C(s)_{1/0}$	-3 457 540	88.76	77.61	-10.49	89.08	-10.92
3	change in the unit price of raw materials	$C(p)_{1/0}$	1 207 620	104.42	-27.11	3.67	104.91	4.91
4	Total:	$C(Q,s,p)_{1/0}$	-4 455 220	86.49	100.00	-13.51	86.49	-13.51

Another area of application of the joint change index should be of analytical calculations of the dynamics of the aggregate CPI levels and intensity of inflationary processes. A separate application of the Index III system can be a sophisticated analysis of the formation of costs in management accounting, as well as modern point of view of cost management and making sound management decisions aimed at saving modes, saving and innovation technologies and/or products.

It should be said about the analytical potential of these calculated indices in relation to the study of the impact of the inflation, increased in recent months, on the level of life of various strata of the population. The inflation process is multifaceted, its nature is similar to chain reactions in the fields of physics, and it can manifest itself in the following areas and positions: 1) price increase; 2) the devaluation of the ruble in conditions of relative stability of the economy; 3) growth of the dollar and the euro in the conditions of absolute instability of the economy; 4) the rise in the cost of gross output and wholesale prices for a unit of commodity weight; 5) the inflated financial "bubble" of the business entity by an order of magnitude above the regulatory/recommended levels in relation to physical assets; 6) a sharp decline in liquidity in all asset types of stock markets; 7) excessive transaction losses, expenses, damages and missed benefits of modern management.

According to experts of the Research institute of statistics of Rosstat, inflation should be cured as a whole, and not by separate measures. The differentiated inflation indices, including equity, currency, and similar indices, constructed by the IJC technology may indicate what measures to take to target inflation. Economic instruments for adequate compensation for inflation losses can be constructed with the help of these indicators.

These indices can can help solve the problem of practical implementation of the methods for adjusting financial statements of an economic entity (for example, in order to assess the market value) in terms of inflation, which is directly related to the calculation of the price index, which is useful for the translation of the financial statements. Therefore, the determination method of the measurement of inflation or the choice of statistical indicators reflecting the amount of inflation processes in the economy of the country is one of the most important stages of development of theoretical and methodical bases of adjustment of financial statements to ensure comparability and validity. The correctness of the subsequent assessment procedures largely determines the scientific validity of the selection of indicators characterizing inflation.

The method of assessing the impact of structural changes on the level of inflationary expectations may be claimed from an unexpected side, since 10 November 2014 the Central Bank of the Russian Federation has changed its focus, and announced the level of inflation and not the rate of the national currency to be the reference point of the monetary policy. The currency corridor, when the megaregulator is buying and selling currency by manipulating the exchange rate, was practiced in the Russian Federation since 1995. Now the key rate became the main tool of management of the money supply, i.e., monetary aggregates of the economy.

Analysis of recommendations on adjusting the financial statements contained in the publications of

Russian authors has shown that the vast majority of them offer for the purpose of adjustments to use the model in constant prices (GPP) and to apply CPI as the inflation index in the framework of this model. However, a number of publications containing methodological issues affecting corrective procedures in terms of inflation based on the CPI may contain controversial provisions and opinions, requiring an open debate.

The formula of the joint changes index from expression (14) can also be represented in its extremely useful modified form via the analog indices of Varzar, which can assess changes in secondary traits: specific expenses of the working capital (s(j)) and unit prices for raw materials and supplies (p(j))

$$\Im_{C(\Delta Q,\Delta s,\Delta p)1/0} = \Im^{(G)}_{s1/0} \times \Im^{(G)}_{p1/0}, \quad (15)$$

In this case, the initial entry of the simple index of total costs on working capital from the expression (15) takes a form that is perfectly finished, almost classical, and, more importantly, convenient for the analytical work and subsequent economic interpretation:

$$\Im_{C(Q,s,p)1/0} = \Im_{C(Q)1/0} \times \Im_{C(s)1/0} \times \Im_{C(p)1/0} \times \Im^{(G)}_{s1/0} \times \Im^{(G)}_{p1/0}.$$

(16)

The above material is not presented in didactic literature and is a methodological development of the authors. This approach to the construction of III Index system may be useful for economists, practitioners, financial and market analysts, and researchers who wish to learn the index method as a reliable statistical tool of subject socio-economic studies, in particular, the technique of the analysis of the joint changes index in different substantive modifications.

Conclusions

The IJC technology allows not only theoretically reliable calculations, but also to get more subtle (although more laborious) measurements in the framework of applied research and operational analytics with any conceivable set of signs of the causal factors of any dimension, without specially resorting to statistical techniques of multiple correlation and the construction of regression equations.

In particular, it is noteworthy that calculations of the effect of physical volume of production (natural-material composition of products, a structural component), unit costs of circulating assets and material costs presented in columns 8 and 9 of table. 2 differ somewhat from the estimates obtained by the routine method. However, the authors believe a more accurate assessment f the assessment of cost inflation, produced by a specific unit of the company obtained using the IJC technology, to be more accurate.

The technique demonstrated gives the opportunity without the use of a particularly complex mathematical apparatus to produce generalization to k-dimensional case, since the goal of any didactics implies subsequent synthesis. The approach also contains potential assessment of the impact of the included factors not only in the traditional relative form (in percentage), but, importantly, in absolute value terms, using differential forms of special analytical indexes, which is more convincing for the management of analytical services and top management of the enterprise.

Abstract

Aquaculture has an enormous contribution to worldwide food production, being one of the fastest growing food sectors and a significant economic activity for many countries. In 2012, aquaculture contributed with 42.2% to total fish production. Due to the continuous growing of world population and of rising incomes and urbanization, aquaculture will continue this impressive development, being expected to overcome capture fisheries production till 2030. The continued growth of aquaculture contributes to increasing pressure on natural resources, water, feed and energy. Fish production generates considerable amounts of effluent which may have an adverse environmental impact. Generally, aquaculture effluents include uneaten feed, faeces and other organic and inorganic compounds. Because aquaculture depends largely upon a good aquatic environment, mainly the success of developing aquaculture needs to be related to it. In the context of the aquaculture expansion it is essential that the aquaculture technologies be ecologically sustainable and to respect environmental legislation. Mostly, the impact of aquaculture on environment mainly depends on reared fish species, rearing and management techniques, location and also, local environmental conditions. In this context, the aim of this present paper is to present a literature investigation regarding the world aquaculture status, together with its potential effects on the environment.

Keywords: environmental impact, sustainable aquaculture, aquaculture production systems.

Introduction

Fish is considered a food with a high nutritional value, providing an important source of protein and a wide variety of vitamins (such as D and B2-riboflavin), minerals (iron, zinc, iodine, magnesium, and potassium) and poly-unsaturated omega-3 fatty acids. According to the report of Food and Agriculture Organization from 2014, in the year 2010 fish accounted 16.7% of the global population's intake of animal protein and 6.5% of all protein consumed. Taking into consideration

that world's population keeps growing during next decades and global life standards, respectively animal protein need rises, fish demand will certainly growth. Because the wild fish captures are already exploited at maximum level, a large part of those new demands must be satisfied through aquaculture activity. As a result, aquaculture has generated a great interest from the international scientific community, supplying the concerns regarding the increase of sustainability and profitability by different methods.

Aquaculture represents the farming of aquatic organisms including fish, mollusks, crustaceans and aquatic plants. According to the Food and Agriculture Organizations, 2014, aquaculture is the fastest growing animal food sector in the world. Food and Agriculture Organizations, (2000) mentioned that in the present, aquaculture supplies an estimated 49% of all fish that is consumed by humans globally and is expected to contribute to more than half of the global fish consumption till 2030.

Although aquaculture has many benefits (providing food and ensuring jobs for humans) a big concern which is facing it is represented by its environmental impact and water quality degradation. Acoording to Guangjun et al (2010), if this sector is not well managed we may experience some unreasonable phenomena such as: the random discharge of aquaculture wastewater, the abuse of medicines, and the escaping of aquatic animals, which have serious influences on the environment.

A. The state of World and EU Aquaculture. World food fish aquaculture production expanded at an average annual rate of 6.2% in the period 2000–2012, slower than in the periods 1980–1990 (10.8%) and 1990–2000 (9.5%). Between 1980 and 2012, world aquaculture production registered a slight increase with an average rate of 8.6 % per year. In a report published by Food and Agriculture Organizations (2014), in the year 2012, this sector reported a record registering almost 90.4 million tonnes, including 66.6 million tonnes of food fish and 23.8 million tonnes of aquatic algae, being estimated for 2013 a production of 70.5 million and 26.1 million tonnes, respectively. The World per capita apparent fish consumption increased from an average of 9.9 kg in the 1960s to 17.0 kg in the 2000s and 18.9 kg in 2010, with preliminary estimates for 2012 pointing towards further growth to 19.2 kg (Food and Agriculture Organizations, 2014).

The species that dominate world aquaculture are aquatic plants, shellfish, herbivorous fish and omnivorous fish. Also, a rapid increase is obvious for marine aquaculture of carnivorous species, especially salmon and shrimp and other marine finfish (Food and Agriculture Organizations, 2014). The most widespread type of aquaculture in the world is represented by the farming of tilapias, Pangasius and other cichlid species. (Food and Agriculture Organizations, 2014).

The global distribution of aquaculture production in all regions and countries with different levels of economic development remains unbalanced. Asia dominates this production, accounting 88.39% of world aquaculture production in 2012, this being determined by the significant contribution of China (Food and Agriculture Organizations, 2014).

Compared to world aquaculture production, which continues to rise, European aquaculture is in a period of stagnation. EU contributions to world aquaculture production have been decreasing significantly over time in both volume and value terms, representing only 1.9% and 3.5% of world production in 2012. According to Eurostat 2014, aquaculture production by the European Union Member States was approximately 1.25 million tonnes of live weight in 2012, almost the same as in 2011. This represented a decline in aquaculture production of about 11% after the relative peak of 2000.

Mainly, the most valuable species produces in EU are Atlantic salmon, oysters, sea bream, sea bass and trout. The main species produced in freshwater is represented by trout. Also, carp is another important species mostly produced in Eastern Europe, where the main producer is Poland covering 39% in terms of total value (Food and Agriculture Organizations, 2014). According to Eurostat (2014) the three largest aquaculture producers among the EU Member States were Spain, the United Kingdom, and France, which together accounted for more than half (54%) of the EU aquaculture

production in 2012.

Aquaculture production systems. Aquaculture systems can be classified in extensive, semi-intensive, intensive, or highly or super intensive depending upon the number of organisms grown per volume of water and the water source and supply. Extensive aquaculture is practiced without feed or fertilizer inputs. In semi-intensive aquaculture fertilizers can be added to increase the natural productivity and the water quality can be improved using additional aeration. In intensive aquaculture high densities are practiced using aeration, full feed, and chemical supplements, in order to promote the health of the organisms grown. In principal, freshwater aquaculture is practiced either in fish ponds, pens, cages or, on a limited scale, in rice paddies, in high flow-through tanks or in recirculating aquaculture systems (RAS), brackish aquaculture is done mainly in fish ponds located in coastal areas and marine culture employs either fish cages or substrates for mollusks and seaweeds such as stakes, ropes, and rafts (Food and Agriculture Organizations, Aquaculture Systems and Practices: a Selected Review, 1989).

Pond aquaculture. Pond aquaculture represented the oldest fish farming activity and involves maintaining the environmental conditions at the same level of the technological requirements of fishes. In these systems fish are raised at low densities, mainly because of lack of additional feeding, fish feeding on aquatic animals reared is strictly resulting from natural productivity and due to the difficulty to control water quality. Usually, in order to improve natural food are applied organic and inorganic fertilizers, which contribute to developing natural developing micro and macro flora, food that will support fish populations or other aquatic animals. Higher production can be obtained in the condition of supplementary feeding and higher stocking densities, but this supposes water aeration. According to SRAC (Southern Regional Aquaculture Center), Publication No. 163/1997, in a pond without aeration, it can be obtained from 226 kg to 680 kg of fish per 0.40 ha. Instead, in a pond with aeration, it can be obtained around 1133 kg to 1814 kg of fish per 0.40 ha. To increase the profitability of these systems is indicated to combine both fertilizer and supplementary feeding.

Between the main disadvantages of these systems, we emphasize: require large volumes of water, large land/pond area, due to the use of organic and inorganic fertilizers may appear eutrophication of the waters, incapacity to guarantee the safety of the product to consumer, because ponds systems are open-air there is always a risk of water contamination. But, according to Verdegem & Bosma (2009) if this systems succeed a better optimization of water consumption and feed management they could triple production without increasing freshwater usage. That's why, to increase the economic efficiency of this systems it`s crucial to optimize water consumption, a good solution being the integration into other production systems and also applying of a production management focused on sustainability.

Aquaculture in Raceway. Raceway, also known as a flow-through system, represents enclosed systems which are based on the continuous water flowing through the culture tanks. Because in these systems water enters at one end and flows through the raceway in a plug flow manner, the best water quality exist only at the head of the tank, where the water enters, and then deteriorates along the axis of the raceway toward the outlet (Timmons and Ebeling, 2013). In comparison with the ponds these systems have several advantages, as higher stocking densities, improved water quality, feeding and harvesting are done more easily, less off flavor and an easier way to control disease problems. Fish metabolites are carried out with the effluent while settleable particulate wastes can be collected by settling or less frequently by other means of filtration. Optionally, this type of systems can be integrated into agricultural production, a fraction of the waste process water used in the irrigation of different agricultural areas.

Between the main environmental concerns of these systems we mention eutrophication as the main consequence of increased nutrient loadings (faecal and uneaten food waste), the use of chemicals to control parasites and disease. Also, a big disadvantage of raceways is related to the needs of constant flows of water with a high quality.

Cages and Pens. Cages are boxes shaped enclosure which floats, is suspended, or sits on the bottom

of a larger water body. Usually, the cages size varied from 1.0 m^3 to 1,000 m^3. Usually, pens are much larger and serve as enclosures to hold organism for grown. In pens, organisms have free access to the bottom within the enclosed area. Growing and production of farmed aquatic organisms in caged enclosures has been a relatively recent aquaculture innovation. Primarily, these systems have been associated with the culture of salmonids, but due to the rapid expansion of aquaculture in the last 20 years this sector has grown very rapidly. Generally, cage culture is suitable for the growing of carnivorous species with a high economic value (Atlantic salmon, Coho salmon and Chinook salmon Japanese amberjack, red seabream, yellow croaker, European seabass, gilthead seabream, cobia, rainbow trout, Mandarin fish) (Tacon A. et al 2007).

The main advantages of cage culture are associated with the use of existing water and the fact that doesn`t require land ownership, the related capital costs being quite low making this technology the most economical culture. Also, a big advantage it`s represented by the possibility to move into optimal rearing environments and sheltered areas.

Between the disadvantages of the system, we mention the fact that these systems are permanently exposed to foul weather conditions making impossible the controlling of physical-chemical water and also the environmental impact on water quality generated by these systems. Also, according to Sugiura et al (2000) and Tacon A. et al (2007), cage cultures are vulnerable to poaching and vandalism and to higher risks of fish escaping.

Aquaculture in recirculating systems (RAS). Recirculating Aquaculture Systems are used for fish farming or other aquatic organisms by reusing the water in the production by mechanical, biological chemical filtration sterilization, oxygenation, and other treatment steps. That's why RAS systems represent an alternative to pond aquaculture due to low water consumption (Verdegem et al 2006) better opportunities for waste management and recycling of nutrients (Piedrahita, 2003) and due to the easy way to control the spread of disease (Summerfelt et al 2009; Tal et al 2009). RAS are intensive production systems than most other types of traditional aquaculture systems (Timmons and Ebeling, 2013) and are the most compatible with environmental sustainability (Martins et al 2010), due to the production of small quantities of wastes and of water reuse. However, the main disadvantages of these systems are high capital and operational costs and requirements for very careful operational management. That's why this type of systems are justified only for growing high-value species such as sturgeon, pike, perch, eel, catfish, tilapia, etc.

B. Impacts of aquaculture on the environment. Due to rapid expansion and to continued pressure on natural water resources, energy and feed, aquaculture can produce different impacts on the environment. Aquaculture can exert both positive impact and negative on the environment. Usually, the quality and quantity of waste from aquaculture, as well as the environmental impacts of aquaculture, vary with farmed species, the management practices used and location of the production system but also on feed quality and management (feed composition, feed ration and feeding method) (Preston et al 1997; Wang et al 2005; Podemski C.L. and Blanchfield P.J. 2006). Among the major effects of aquaculture on the environment in this paper we refer to:

- Effluent discharges;
- Effects of other discharges from aquaculture (e.g. fertilizers, chemicals, and medicines);
- Escapes from fish farms and potential effects on wild populations.

Effluent discharges. Aquaculture effluents contain dissolved and suspended solids that have biochemical oxygen demand (BOD), ammonia and nutrients phosphorus (P) and nitrogen (N) that are derived from fish excretion, faeces, and uneaten feed, and specific organic or inorganic compounds (i.e. therapeutics). Between all these components a special attention is directed towards nitrogen and phosphorus which are considered the main pollutants of intensive aquaculture (Hakanson et al., 1998). These components are a real source of pollution and if they are developed at high level can cause of eutrophication (González et al 2008), resulting in occurrence of the harmful algal blooms (Pearl H. W. 1997; Goldburg Rebeca and Tracy Triplett et al 1997) and the depletion of oxygen due to the increase of microbial activities (Diaz et al 2008).

It is obviously that feeding is the main source of waste output from aquaculture, due to the high amounts in fishmeal (FM) which is rich in P. In fact, Ackefors, (1999) said that the content of phosphorus and nitrogen in the feed and the feed conversion rates are most important in assessing environmental impacts of aquaculture. According to Jackson et al (2003) and Schneider et al (2005) only 20% to the cultured organism is retained as biomass while the rest is incorporated into the water column or sediment. Moreover, Pierhadrita, (2003) says that nitrogen and phosphorus retention range between 10-49% and 17-40% respectively, while from faeces N and P are released from 3.6% to 35% and 15% to 70% respectively. Lastly, dissolved N and P excretions range from 37% to 70% respectively. Nowadays, modern aquaculture is based mostly on the feeding of manufactured feeds (extruded pellets) reducing the phosphorus excretion. For example, in a diet for salmon, with 40% protein, 30% lipids, 13% carbohydrate and a energy content of 19.2 MJ kg-1, the nitrogen content is around 7%, aspect which makes possible to use fat for energy (instead of protein) and excreted of smaller volumes of nitrogen compounds (Pillay, 2004). That`s why it is very important to know the ingredients from the feeds and to balance these nutrient in order to improve the nutritional quality. Cho et al (1991), says that the goal of aquaculture is to produce feed very well suited to the nutritional needs of the fish so that the maximum growth can be achieved with minimum waste, particularly phosphorus and nitrogen. So, according to Youssouf A. et al (2012), a way to reduce P waste produced by aquaculture is to replace the FM with FM substitutes that contain lower P, without affecting the growth performance of fish. Also, Ayoola A. (2010) suggest that a possible alternative of protein sources, can be represented by animal proteins from rendering or slaughter, plant protein concentrates and novel proteins such as algae, yeast, dried distillers grains with soluble (DDGS) and insect meal.

Besides feed composition, others factor responsible for pollution effluent from aquaculture is the type of the culture systems and the practiced stocking densities. In general, the effluent resulting from aquaculture raceway is more polluted in comparison with ponds effluent, cages and pens, mainly because water passes quickly through raceways and dissolved and suspended matter are flushed out. Generally, wastes emitted from cages and raceways are quickly diluted but also can generate changes in sediment structure and function (Beveridge M. et al., 1997). On the other hand effluent from RAS systems, it is around 10% (daily water exchange) of total system volume per day, but RAS produce a concentrated waste.

Another important issue which will receive increasing attention is the practice stocking densities. High stocking densities suppose the concentration of many organisms in a low water volume, increasing the waste productions and thus increasing the concentration of phosphorus and nitrogen compounds from water. Also, not all fish species have similar metabolism having different capacities to process energy and nutrients, and that`s why choosing the suitable species for growth and the suitably grown system can be a good solution to protect the environment. Also, Manoochehri et al (2010), mentioned as a measure to reduce nutrient wastes or to avoid or reduce any negative environmental impacts a careful monitoring and management of aquaculture effluents.

Effects of other discharges from aquaculture (e.g. fertilizers, chemicals, and medicines). Besides the wastes, aquaculture effluents may contain chemicals (fertilizers, disinfectants and chemotherapeutants pesticides, antibiotics). Usually, fertilizers are used in aquaculture ponds, in order to increase the primary productivity by stimulating the phytoplankton growth. For that, a very important aspect is to establish the needed doses. These doses may be determined only from the knowledge of the chemical composition of the water and the physical-chemical characteristics of its bottom. Generally, in aquaculture are used organic fertilizers or inorganic fertilizers, or a combination of both. Inorganic fertilizers are an inorganic compound which contains nitrogen, phosphorus, and potassium. However, fertilizers, whether they are artificial or organic, can cause serious problems if they contaminate water or are added in excess, contributing to the deterioration of water quality and implicit to discharged effluents.

According to Okomoda V. (2011), in modern aquaculture, especially in high stocking density aquaculture, to prevent diseases, eliminate harmful biota, disinfect and restrain polluted and damaged

water, multiple chemicals and medicines are used. In the lasts years, the use of antibiotics has grown, even their use remains still controversial. Generally, the antibiotics are incorporated in fish pellets and due to uneaten feed go straight into water and bottom. Also, they can enter in water through faeces and by urine excretion. In fact, there are researchers who indicate the approximately 70-80% of the drug ends up in the environment (Samuelsen, Torsvik and Erik, 1992; Lalumera et al 2004). Mainly, in aquaculture antibiotics are used for therapeutic purposes and as prophylactic agents (Zheng et al 2012), the most frequent fish infections treated with antibiotics are skin ulcers, diarrhea and blood sepsis (Food and Agriculture Organizations, 2005).

Although their use is carefully indicated, there are cases when their discharge into the aquatic environment can lead to serious damages, due to the fact that they came in direct contact with water and soil. (Boxall 2004). These risks are associated with the direct toxic effects (on benthic micro and meiofauna, algae, plankton and other aquatic organisms) and more subtle effects including potential modification of bacterial communities (and the promotion of antibiotic-resistant organisms) (Marine Strategy Framework Directive, 2015). However, the use of antibiotics in aquaculture remains still difficult, because they must be administered directly into the water, and that's why should be taken into account a number of considerations such as environmental integrity, the safety of fish and the aquatic products intended for human consumption.

Escapes from fish farms and potential effects on wild populations represent another big issue of aquaculture, with detrimental effects on the environment. According to a report published by The Scottish Association for Marine Science and Napier University Scottish Executive Central Research Unit in 2002, escapees from fish farms may interbreed with wild population resulting in losses of genetic variability, including loss of naturally selected adaptations, thus leading to reduced fitness and performance. Also, escaping of fish from farms can be responsible for the spreading diseases and others pathogens. It is necessary for a better understand the relationships between disease and both as a means of preventing environmental economically serious disease outbreaks and indirectly promoting the need for better environmental management (Pullin et al 1993). In cases of cages, pens or other systems which release the untreated effluent directly into the water the possibility of transmitting diseases to wild fish stocks is quite high. The main way of introducing diseases is the transfer of infected farmed juveniles to these systems, or through infected food equipment, and through water streams (Ruiz et al 2000, Murray et al 2005, Salama et al 2011).

Conclusions

Aquaculture represents the sector with an important economic activity being situated on top of the food production industry. Increasing customer demand for aquaculture products, together with increasing environmental and also, the costs associated with land and water will determinate the producers to develop their technological facilities or to implement new solutions in order to assure the practice of high stocking densities and to meet the market demands while taking into consideration environmental protection.

In order to protect the environment, aquaculture activities must be conducted sustainably, with minimal impact on the environment. In fact, the aquaculture industry is already working on this requirement, which in many countries has reached an impasse. In conclusion, to develop a sustainable growth of aquaculture is needed to be profitability, economic development and to practice a good waste management. There are many measures which can be taking in order to reduce the environmental impact of aquaculture, as: reducing as much as possible food losses, the adoption of management strategies of discharged effluents, like the utilization of the recirculating systems or systems with low or zero water exchange, the revalorization of the wastes by integrating in hydroponic systems for plants production or for composting for garden applications. Also, it is important to ensure sustainable sourcing of feed, to avoid escapes by adopting technical standards, to minimize biodiversity impacts and to reduce the impact of chemicals and medicine use, particularly antibiotics.

Abstract

After the global financial and economic crisis, the competition in the banking market has intensified significantly. A common suggestion is that banks have to focus on the needs, wants, expectations and requirements of clients. To be successful in this competitive fight, banks ought to respond to the growing competition in the banking market by usage of market segmentation techniques. Although banking sector have been a topic of interest to many studies and researches since 1960s and 1970s, students as a specific banking segment was not for a long time in the center of attention of researchers. This article focuses on the students as a specific segment of banking sector, their wants and needs. This paper is based on a data that were gathered through author's research and processed with appropriate statistical methods. Results of the author's research indicate that students have a positive attitude towards modern technology they are not willing to pay high bank fees and use mainly several banking products and services. Author stated several hypotheses to tested relationship between gender and other variables that were confirmed or rejected at the 99% confidence level.

Keywords: segment, segmentation, students, banking sector

Introduction

Changes in the banking sector, such as implementation of new technologies, increasing number of products and competitors, financial crisis, etc. have resulted in new environment with strong competition (Mylonakis 2007). If banks want to be able to face strong competition, they have to follow new trends and put emphasis on marketing activities and satisfying wants and needs of their clients. Satisfying customers' wants and needs is considered as one of the major elements of marketing. With growing competition marketing plays an essential role for every institution. Any institution in any industry have to incorporated marketing management and market segmentation in their activities as an essential element for success in business (Premkanth 2012). Marketing and customer orientation concept of marketing claims that the main purpose of the organization is to discover wants and needs of customers (target markets) with the aim to be able to satisfy those needs and wants more quickly and effectively than competitors (Areo 2015, Slater, Narver 1998, Hensley, Stock 1998, Kotler, Keller 2011). Understanding customers' expectations, needs and wants is considered as a first requirement for market segmentation (Premkanth 2012).

Lots of authors point out that segmentation and adaptation of marketing concept is very important for banks' strategy (Areo 2015, Mokhlis, Mat, Salleh 2008, Premkanth 2012, Ijevļeva 2013). Areo (2015) states that the main aim of any bank is satisfying customers' needs and wants by delivering services according needs and wants of different segments. If any bank wants to be successful in delivering services to its clients, it is necessary to understand needs and wants of particular segment in detail (Areo 2015). Marketing segmentation of students is emphasized by Tišlerová and Žambochová (2011).

The banking industry is transformed by new internet and smartphone trends and applications that are transforming bank products and services (Gupta 2008). These modern trends are used mainly by segments of young people and students (Bain & Company 2015). Eurostat statistics and Bain statistics show that the internet banking is used mainly by students (16-24 years) and young people.

More young people use internet banking in the Czech Republic in comparison with the European Union. 67% of the Czech people in the age group 25-34 uses internet banking. In the European only 62 % of the people in the same age group use internet banking (CZSO 2015). The highest penetration of mobile banking is in the age group 16-34 years (Eurostat 2015, Bain & Company 2015).

We can say that young people and students are a special segment for banks. This fact is reflected in many researches and articles. Students as one of the specifics segments for banks are mentioned in papers of Mokhlis, Mat and Salleh (2008), Hinson, Osarenkhoe and Okoe (2013), or Chigamba and Olawale (2011). Chigamba and Olawale (2011) point out that mainly university students represent one of critically important segments for banks. On the other hand students are not specific segment only for banks, but they have their specific requirements in other sectors – for example logistics and transportation (Ližbetinová, Kampf, Ližbetin 2012).

This article and author's research represented in this paper focuses on the students as a specific segment in the Czech banking market, on the wants and needs of this segment, services and products required by this segment, etc. Since the internet is considered as a social phenomenon of our time (Stellner, Vokoun, 2014), author will focus on the internet banking in the research, too. Czech banking sector, where author carried out her research, is quite stable. 46 national and international banks operated in the Czech market. In comparison with year 2009 there is seven more banks operating in the Czech market. The time series of the number of the banks operating in the Czech market is shown in the graph 1 bellow.

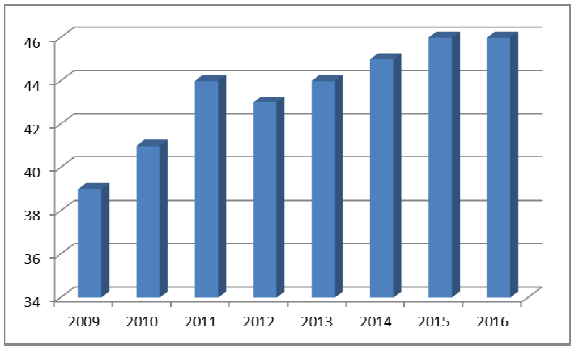

Fig. 1: Number of banks in the Czech market, source: ČNB 2016

Literature Review

The main aim of any bank is satisfying customers' needs and wants by delivering services according needs and wants of different segments. If any bank wants to be successful in delivering services to its clients, it is necessary to understand needs and wants of particular segment in detail (Areo 2015). Lots of authors point out that segmentation and adaptation of marketing concept is very important for banks' strategy (Areo 2015, Mokhlis, Mat, Salleh 2008, Premkanth 2012, Ijevļeva 2013). The understanding of the necessity of the market segmentation in bank industry is not a new phenomenon as well as the idea of segmentation. The idea of segmentation dates back to the 1930s and is connected with works of Chamberlain, or Robinson. The concept of Market segmentation was first defined in detail in 1956 by Smith (Ijevļeva Ijevlava 2013). We can find researches focusing on the segmentation in bank industry dated back to 1970s or 1980s – for example in the papers of Anderson, Cox and Fulcher (1976). Since this article focuses on a specific segment of banking sector – students, first of all we will define the term segmentation and segmentation criteria in banking sector.

There are different types of segments and many different types of criteria (factors) used for segmentation in banking sector – demographic factors, social factors, geographic factors, psychographic factors, etc. (Mylonakis 2007, Stafford 1996, Premkanth 2012, Anderson, Cox and

Fulcher 1976, McDougal, Levesque 1994, Machauer, Morgner 2001, Harrison 1994, Clarkson, Stone, Steele 1990, Ijevļeva Ijevlava 2013).

Psychological and psychographic characteristics are used in the paper of McDougall and Levesque (1994), or Beckett, Hewer and Howcroft (2000). Beckett, Hewer and Howcroft (2000) used psychological and psychographic factors for creating a model of consumer behavior during the purchase of banking services. Based on the literature search we can state that the most used segmentation factors in the banking industry are demographic and social-economic factors. As demographic segmentation factors are mainly used age, gender, marital status, family life cycle, or origin. For example Boyd, Leonard and White (1994) focus in their research papers on the age, gender and marital status. In spite of the fact that some authors – for example Harrison (1994), or Machauer, Morgner (2001) conclude that demographic segmentation criteria provide only little insight to the customer behavior in banking services and suggest the usage of multidimensional model, lots of other authors consider demographic factors as important segmentation factors for banking industry. Machauer and Morgner (2001) used attitude and expected benefits as segmentation criteria in their research. The importance of demographic factors in bank industry is highlighted in the paper of Stafford (1996), Mylonakis (2007), Boyd, Leonard and White (1994), or Clarkson, Stone and Steele (1990). Clarkson, Stone and Steele (1990) claim that financial services and the requirements of consumers vary mainly with the age as one of the most important segmentation factors. Stafford (1996) point out that in spite of the fact if bank uses psychographic, economical, or other segmentation factors bank must understand demographic characteristics of the target market.

Based on the literature review we can state that segmentation plays very important role in the banking sector and that it is necessary to focus on the needs and wants of each target segment separately. Ijevļeva (2013) claims that banks should concentrate to a particular target segment in the banking market. Furthermore literature search revealed that students are very often in the focus of researchers as a specific segment of the banking market for example Mokhlis, Mat and Salleh (2008), Ukenna, et al. (2012), Al-Fahim (2012), Hinson, Osarenkhoe and Okoe (2013), or Chigamba and Olawale (2011)

Methodology

This paper focuses on one of the specific bank segments – students. The main aim of this article is to discover needs, wants and expectations of this specific segment. Author focuses on the banking products and services required by this segment, usage of internet and mobile banking, willingness to pay fees, etc.

In order to investigate requirements of this segment for banking services, author used a questionnaire that was submitted to the students. The total number of questioned respondents was 150. The questionnaire was divided into two parts. The first part of the questionnaire focuses on the information about expectations and requirement of students from their bank. Respondents were asked about bank products and services, usage of internet banking, mobile banking and mobile applications, visiting banks, acceptable bank fees, different services that respondents require from the bank, etc.

The second part of the questionnaire includes personal details of respondents.

Author used a filter question to exclude respondents who do not use any banking services.

The sample includes 50% of female and 50% of male; the average age of respondents was 23.5 years.

The collected data were processed with classical mathematical-statistical methods of data evaluation – especially through calculating the absolute and relative frequency, mean, weighted arithmetic mean, standard deviation, etc.

The chi-square test represents statistical test that is commonly used to test independency of categorical data for comparison of observed data with expected date to a specific hypothesis. Author will use the chi-square test to find out whether the opinion of both groups of respondents (male and female) significantly differs in the usage of banking products with higher level of usage than 50%. The formula for calculation of chi-square test follows.

$$\chi^2 = \sum_{i=1}^{k} \frac{(X_i - Np_i)^2}{Np_i}$$

Author stated two hypotheses for the research . The null hypotheses H0 and alternative hypotheses H1 stated for author's research follows:

$H_1 0$: Usage of banking products and services is independent on the gender

$H_1 1$: Usage of banking products and services is not independent on the gender

$H_2 0$: Willingness to pay banking fees is independent on the gender

$H_2 1$: Willingness to pay banking fees is not independent on the gender

Results and Discussion

First of all, respondents were asked about basic information concerning banks, commitment to bank, number of banks accounts, etc. The results are presented in the following table.

Table 1: Information about students' current accounts, Source: author's research

		Absolute frequency	Relative frequency
How many current accounts do you have	0	0	0
	1	128	85,333
	2	21	14
	3 and more	1	0,667
How long do you have your current account	1 year	2	1,333
	2 years	10	6,667
	3 years	13	8,667
	4 years	50	33,333
	5 years	65	43,333
	6 years and more	10	6,667

All asked students have at least one bank account at one bank. More than 85% of respondents have only one current account. All respondents that have more than 1 current account provided the answer that they have current banks account at different banks. The average time of having a current account is 4.3 years. More women than men stated that they have more than 1 current account.

Since respondents of the author's research are university students; the average age of respondents was 23.5 years and average time of having a current account is 4.3 years. This fact is quite clear with regard to the possibility of opening own current account until age of 18. Till 18 years the only possibility is so called Children's account with the consent of the legal representative (one of the parents). The following figure shows how long students use their current account.

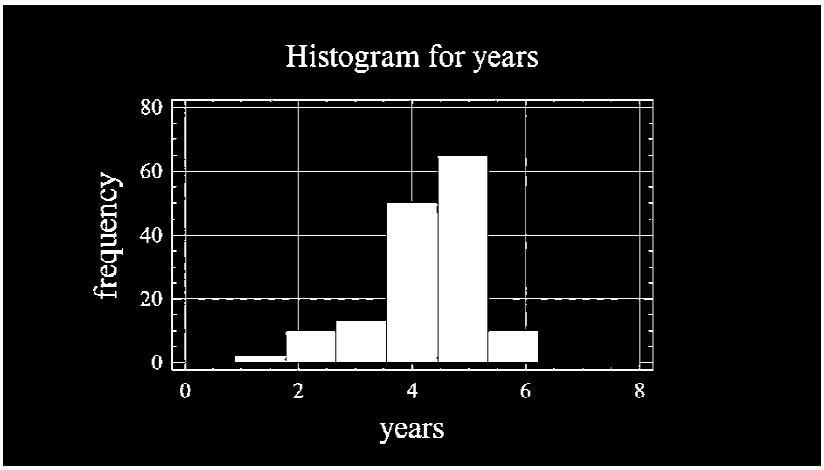

Fig. 2: Histogram of period of current account usage

At the second part of the questionnaire respondents were asked about banking products and services that they use. The following table summarized banking products and services used by students.

Table 2: Banking products and services, Source: author's research

Banking product, service	Absolute frequency		Relative frequency (%)	
	Male	Female	Male	Female
Internet banking	75	75	100,00	100,00
Home banking	5	3	6,67	4,00
Telephone banking	12	23	16,00	30,67
Banking application for smart phones	68	51	90,67	68,00
Debit card	75	75	100,00	100,00
Credit card	12	22	16,00	29,33
Contactless debit card	51	46	68,00	61,33
Current account	75	75	100,00	100,00
Overdraft	15	11	20,00	14,67
Savings account	8	14	10,67	18,67
Term deposit	2	4	2,67	5,33
Consumer loan	2	3	2,67	4,00
Building savings	10	28	13,33	37,33
Mortgage	0	2	0,00	2,67
Life insurance	46	57	61,33	76,00
Household insurance	3	2	4,00	2,67
Car insurance	57	20	76,00	26,67
Travel insurance	69	73	92,00	97,33
Cash back	4	9	5,33	12,00
Loan for real estate	0	0	0,00	0,00

All respondents (male and female) uses internet banking, current account and debit card. More than 50 % of respondents use banking application for smart phones, contactless debit card, life insurance and travel insurance. 76 % of male uses car insurance, too. But only 26.67 % of female uses car insurance. For products with higher level of usage for male and female the chi-square test will be calculated.

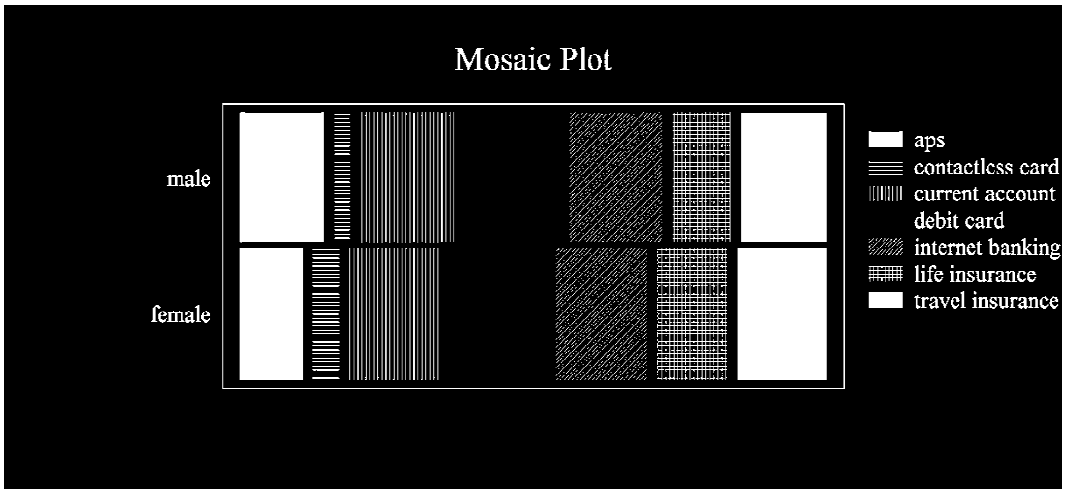

Fig. 3 : Mosaic plot of selected services

In the Fig. 3 we can see the distribution of usage of selected services is for male and female. Precise conclusions will be taken on the basis of the chi-square test.

Chi-Square Test

Chi-Square	Df	P-Value
6.58	6	0.3612

The chi-square test performs a hypothesis test to determine whether or not to reject the idea that the usage of products is independent on the gender. Since the P-value is greater than 0.01, we cannot reject the null hypothesis that the usage of banking products and services is independent on the gender at the 99% confidence level.

From the analysis is clear that for several products – for example car insurance and building savings the answers of male and female differ, therefor the chi-square test will be calculated for these banking product separately.

Chi-Square Test

Chi-Square	Df	P-Value
23.82	1	0.00
21.89	1	0.00 (with Yates' correction)

In this case since the p-value is less than 0.01, we can reject the null hypothesis that usage of these products is independent on the gender of respondents at the 99% confidence level. The p-value with Yates' correction was used because it should be more accurate for 2-by-2 table.

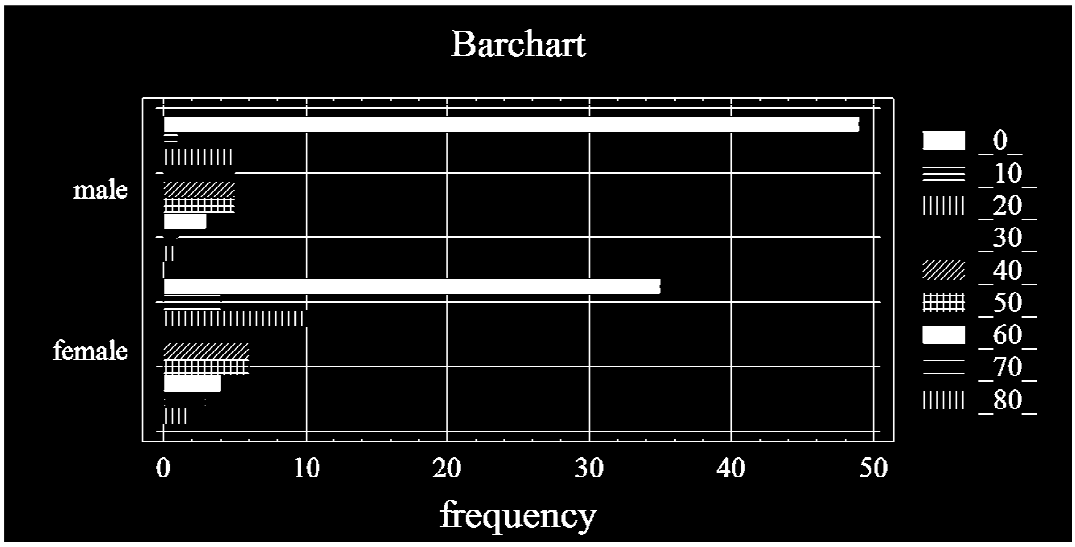

Fig. 4 : Barchart for current account fees

The barchart in the Fig. 4 shows the willingness of respondents to pay banking fees for current account. Respondents were asked how much money they are willing to pay for their current account. As we can see the most of the respondents is not willing to pay banking fees for current account.

The summary statistics concerning willingness to pay banking fees follows

	female	male
Count	75	75
Average	20.2703	13.9189
Standard deviation	24.7161	21.8223
Minimum	0.0	0.0
Maximum	80.0	80.0
Stnd. skewness	3.07119	4.62392
Stnd. kurtosis	-0.884931	0.894545

This table shows summary statistics for the two samples of data. Other tabular options within this analysis can be used to test whether differences between the statistics from the two samples are statistically significant. Of particular interest here are the standardized skewness and standardized kurtosis, which can be used to determine whether the samples come from normal distributions. Values of these statistics outside the range of -2 to +2 indicate significant departures from normality, which would tend to invalidate the tests which compare the standard deviations. In this case, both samples have standardized skewness values outside the normal range. Both standardized kurtosis values are within the range expected.

For detail analysis to discover differences in respondents' opinion chi-square test were used.

Chi-Square Test

Chi-Square	Df	P-Value
7.46	8	0.4881

Based on the results of chi-square test, since the p-value is greater than 0.10 we cannot reject the hypothesis that the willingness to pay banking fees is independent on the gender.

The following table summarizes the basic information about usage of internet banking, application for mobile banking and frequency of visit of bank and usage of internet banking.

Table 3: Visiting bank, internet banking and mobile banking apps, Source: author's research

		Absolute frequency		Relative frequency	
		Male	Female	Male	Female
How often do you visit your bank	Once a week	0	0	0	0
	Every two weeks	2	5	1.333	3.333
	Once a month	9	15	6	10
	Every three months	20	31	13.333	20.667
	Once a year	71	69	47.333	46
	I don't visit bank personally	48	30	32	20
Usage of internet banking	2 times a week and more	5	18	3.3333	12
	Once a week	18	29	12	19.333
	Once every two weeks	22	24	14.667	16
	Once a month	24	3	16	2
	Less than once a month	6	1	4	0.667
Usage of mobile banking application	Yes	28	24	18.667	16
	No	47	51	31.333	34

As we can see from table 3 not many students visit bank periodically. Most of them visit bank once a year. And more than one third of male and 20% of female stated that they don't visit bank personally at all. All respondents use internet banking. Woman uses internet banking more periodically than men. This fact is typical not only for students but for the whole population in the Czech Republic. This fact was proved by other author's research (Slabá 2015). Mobile applications are considered as one of the very important phenomenon of the internet society. But less than 20 % of students use mobile applications for internet banking in the Czech Republic for banking purposes.

Conclusion

Based on the author research we can say that there are several specifics in the student segments. Students are not focused for example on the area of mortgages, term deposit, savings account, or house insurance, but have a close relationship to new technologies such as the Internet or mobile banking. Based on the author research and statistics of the Eurostat and the Czech Statistical Office, we can claim that students use internet and the mobile application most frequently than other age groups. All respondents use current accounts from one or more bank institutions. The average time of having a current account is 4.3 years.

Author stated hypothesis to determine whether or not to reject the idea that the usage of products is independent on the gender and whether or not to reject the idea that the willingness to pay banking fees is independent on the gender. The first null hypothesis that was tested for two services - car insurance and building savings was rejected at the 99% confidence level. We can say that usage of car insurance and building savings depends on gender. For other tested services the author cannot reject the null hypothesis - Usage of banking products and services is independent on the gender at the 99% confidence level. The last tested hypothesis - Willingness to pay banking fees is independent on the gender cannot be rejected at the 99% confidence level.

Based on the author's research we can say that bank institution should take into account that student segment is a specific segment that is characterized by the age, lack of funds, interest on the Internet and modern technology. Since the importance of loyalty programs has been growing (Solarová 2015), the banks should focus on the possibility of application of specific loyalty programs for students.

Since the author's research revealed that some of the students use current accounts and other services from more than one bank and some of the respondents switched the banking institution in less than 5 years, this fact should be considered as a topic of further author research.

Identification of Stakeholder Profile for Developing Targeted Communication

Author: Ing. Marie Slabá, Ph.D.
University: Department of Tourism and Marketing, The Institute of Technology and Business in České Budějovice, České Budějovice, Czech Republic,
e-mail: slaba@mail.vstecb.cz

Abstract

Changes in marketing communication leads to new perception of marketing communication and promotion itself. Lots of researches and practitioners have been looking for new interdisciplinary conception of marketing communication. Marketing and marketing communication is more and more connected not only with customers, but with key stakeholder groups and some authors use new term stakeholder marketing. This paper focuses on the interconnection of marketing communication and stakeholder theory and possibilities of usage of identification of Stakeholder Profile for developing targeted communication.

Keywords: stakeholder, Stakeholder Circle Methodology, Stakeholder Profile, marketing communication, urgency, power

Introduction

Marketing communication is an element that is associated with the business over 100 years. In spite of this fact promotion and marketing communication dramatically changed during last years and marketers have to look beyond traditional concept of marketing and promotion (Belch, Belch 2014). Marketing has to start to focus more on the integrated marketing communication, specific marketing segments and targeted marketing communication. The integrated marketing communication has been changing since the first formal conceptualization and gaining interest and attention around the world, too (Kliatchko 2005). Integrated marketing communication as well as targeted marketing communication is considered as one of the key elements for successful business (Belch, Belch 2014). Targeted marketing communication and integrated marketing communication is practiced at large scale worldwide. Both of these phenomenon are associated with customer satisfaction, brand loyalty, brand awareness, brand image, etc. (Reid 2013). All these elements depend on how company is able to reveal and understand customers' expectations, wants, needs and requirements (Saeed 2013). In these days it is not enough to focus only on customers in marketing communication activities. Therefore many academics as well as practitioners have been search for new approaches to marketing communication and incorporating not only customers, but the other key stakeholder groups to their communication plans and integrated marketing communication, too (Gurău, 2008).

Contemporary turbulent environment leads to growing competition at market and reflect the growing popularity of stakeholder theory and multidisciplinary stakeholder approach (Varvasovszky, Brugha 2000, Olander, Landin 2005, Payne, Ballantyne, Christoper 2005, Brugha, Varvasovszky 2000). The stakeholder management is nowadays used by lots of companies and incorporated in marketing, marketing communication, management and marketing management. Lots of authors point out that the relationship between stakeholders and organizations is crucial for organization's success (Rivera-Camino 2007, Leana, Rousseau, 2000, Savage, Nix, Whitehead, Blair, 1991) and represents the most appropriate way for success in competitive market as a support tool for marketing and management decision (Yang 2014).

To be able to succeed in this environment and preparation of targeted communication plan, all institutions have to be able to identify their key stakeholders and reveal and analyses expectations, needs and wants of the entire community of stakeholders.

This article will focus on the identification of Stakeholder Profile of key stakeholder groups of selected small-sized company that is used for the developing of the targeted marketing communication plan.

Literature Review

Since this paper focuses on the connection between stakeholder management and marketing communication for the purpose of identification of stakeholder profile needed for effective marketing communication plan, first of all it is necessary to define basic terms from both spheres of interest.

Integrated marketing communication (further only IMC) has passed through long way since its originally initial conceptualization in the late 1980s and early 1990s (Schultz Kitchen, 1997). Till these days there is not any mutually or consistent agreed upon definition, description or process to define IMC (Kliatchko 2008). The first formal definition of IMC that was widely used till 1989 states that 'A Concept of marketing communications planning that recognizes the added value of a comprehensive plan that evaluates the strategic roles of a variety of communication disciplines – general advertising, direct response, sales promotion, and public relations – and combines these disciplines to provide clarity, consistency and maximum communication impact (Duncan, Caywood 1996). From another point of view Duncan defines IMC as 'an on-going, interactive, cross-functional process of brand communication planning, execution, and evaluation that integrates all parties in the exchange process in order to maximize mutual satisfaction of each other's wants and needs (Duncan, Everett 1993, p.39). Kliatchko suggest that definition of IMC should be made up of two main elements – for basic pillars (stakeholders, channels, content and results) of IMC and business process of IMC driven by key stakeholders (Kliatchko 2008). From the Kliatchko point of view it is obvious that the marketing communication and stakeholders are closely connected.

Origins of stakeholder concept dates back to 1970 but the importance of stakeholder theory has been growing in recent years (Brugha, Varvasovszky 2000, Freeman 2010). The term stakeholder has been widely used in academic and scientific paper and researches and therefore we can find different definitions of the stakeholder concept. Most of the definition involved in adopting the term stakeholder in narrower or broader sense (Ruiz-Roqueñi, Retolaza 2012). Freeman claims that stakeholder represents 'any individual or group that maintains a stake in an organization, a claim, a right or an interest' (Freeman 1984, p. 46). Johnson and Scholes define stakeholders as 'individuals or groups who depend on an organization to fulfill their own goals and on whom, in turn, the organization depends' (Johnson, Scholes 2002, p. 132). This definition is very similar to original Freeman's definition of stakeholders - 'any group or individual who can affect or is affected by the achievement of an organization's purpose' (Freeman, 2010, p. 53). Literally speaking Freeman signified in his definition 'anyone who has a stake'.

Elements of stakeholder management are incorporated in many other disciplines especially in management and marketing. Number of authors emphasizes the need to involve stakeholders in marketing and marketing communications. In contemporary literature, new phenomenon – stakeholder marketing can be found. Stakeholder marketing represents 'a concept that arises from the confluence of stakeholder theory with marketing discipline and practice' (Ruiz-Roqueñi, Retolaza, 2010, p. 815). The following table represents selected papers and articles connected stakeholders and marketing.

Table 1: Stakeholders and marketing, author's research

Author(s)	Year	Area of interest
Polonsky	1995	Integrating stakeholders into environmental marketing strategy
Polonsky	1996	Stakeholder management and stakeholder matrix: Potential strategic marketing tools
Payne, Ballantyne, Christoper	2005	A stakeholder approach to relationship marketing strategy
Presenza, Iocca	2012	Stakeholders and event marketing
Maxim	2009	Stakeholders and relationship marketing
Ruiz-Roqueñi, Retolaza	2012	Stakeholder Marketing: A New Orientation
Maletic, M. et al.	2014	Stakeholders and CSR
Hult	2011	Stakeholder Marketing
Maignan, Ferrell, Ferrell	2005	A stakeholder model for implementing social responsibility in marketing
Rivera-Camino	2007	Green marketing strategy: a stakeholder perspective
Clulow	2005	Stakeholders and added value
Huang	2011	Stakeholder analysis for mobile marketing

Since not only Kliatchko in the case of IMC, but lots of other authors (Varvasovszky and Brugha 2000, Yang 2014, Olander, Landin 2005, Payne, Ballantyne, Christoper 2005, Brugha, Varvasovszky 2000, Leana, Rousseau, 2000, Savage, Nix, Whitehead, Blair, 1991, etc) consider stakeholders as a key element of marketing communication, we can state that the connection between marketing and key stakeholders is unchallengeable. Therefore author will focus in the research on the identification of stakeholder profile for successful targeted marketing communication. There are different approaches to the basic factors influencing stakeholder profile. Following table summarizes the most common factors that are connected with definition of stakeholder profile.

Table 2: Factors of stakeholder profile, author's research

Author(s)	Year	Factors
Varvasovszky and Brugha	2000	Interest in the issue, influence/power, position (supportive, non-mobilized, opposed), impact of the issue on actor (low, low-medium, medium, high)
Reed et al.	2009	Interest, influence, power, requirements
Mitchel et al.	1997	Expectation, power, legitimacy, urgency, salience
Ackermann, Eden	2011	Power, interest, influence, expectations, requirements
Bourne and Walker	2006 2008	Influence, direction of influence (outward, sideward, downward, upward), power, proximity, urgency, support, value, action
Bourne	2006, 2008a 2008b, 2010	Influence, expectation, signification, requirements, vested stake, urgency, proximity, power, direction of influence

Methodology

Based on the literature search we can say that there are different approaches to stakeholder management, analysis and definition of stakeholder profile. Lots of authors prefer numeric expression of values influencing stakeholder profile, the other define a stakeholder profile based on verbal description. Since this article focus on the identification of stakeholder profile for developing targeted communication, author decided to use for the purpose of author's research the Stakeholder Circle Methodology developed by Linda Bourne. This methodology offers for the basic description of stakeholder profile numeric as well as verbal equivalent (qualitative and quantitative rating) of all used factors. Based on the literature search author identified the most important elements of the Stakeholder Profile. As stated in the text above, for definition of the Stakeholder Profile of each

stakeholder group author selected the most important aspects based on the Stakeholder Circle Methodology. These factors follow:

- direction of the influence:
  - outward, sideward, downward, upward,
  - internal, external
- importance for the company:
  - ownership, influence, knowledge, interest, impact, rights, source of funds, contribution, source of other resources, committee member
- mutuality – assessment of what stakeholders require from the company:
  - benefits – delivery of benefits resulting from success of company
  - power – to affect success of company, or organizational power
- classification:
  - authorities, rights holder, supplier, manager, team, community
- power:
  - low level of power to influence company
  - informal capacity to cause change
  - partial formal power
  - high level of power to influence company (stakeholder can stopped company's activities)
- proximity:
  - no direct contact with company - stakeholder group is remote from company
  - Active stakeholder groups (clients) with regular contact with company
  - Routinely part-time working stakeholder groups
  - Stakeholder groups with direct proximity in company
- Value:
  - Limited or no stake in outcomes of the company
  - Small indirect stake in outcomes
  - Medium direct stake in outcomes
  - Outcomes of the company are important for stakeholder group
  - Very high stake in company outcomes
- Action
  - No probability to attempt to influence outcomes of the company
  - Low probability to attempt to influence outcomes of the company
  - Stakeholder maybe prepared to influence outcomes of the company
  - High probability and effort to influence outcomes of the company
  - Significant effort to influence outcomes of the company
- Urgency:
  - Little need of activity outside routine marketing communication
  - Planned activities warranted within medium timeframe
  - Planned activities warranted within short timeframe
  - Urgent activities according to the common marketing communication
  - Immediate marketing communication activities that are priority compared to the common marketing communication

Preparation targeted communication depends on gaining support and managing relationships and expectations of all stakeholder groups that are described by categories defined by direction of influence (Bourne 2010, Bourne 2006). Bourne and Kasperczyk state that the above essential data must be defined and taken into account in developing targeted communication to manage and support relationships with key stakeholder groups (Bourne, Kasperczyk 2009). Therefore all these factors will be evaluated by respondents of the author's research.

For the authors research was selected one Czech company that represents small-sized company based on the European categorization of SMEs. The selected company has 35 employees with annual turnover less than 10 million Eur. There are 5 managers in the company who was involved in the author's research. The main research method was semi-structured questionnaire and interviews with

the representatives (managers) of the selected company with the aim of identification of the Stakeholder Profile based on the previous mentioned list of factors for key stakeholder groups that could be used to prepare targeted communication with these stakeholder groups. The main aim of this paper is to identify the most urgent stakeholder groups in respect of targeted marketing communication based on the Stakeholder Profile developed based on the Stakeholder Circle Methodology.

Author stated following research statement:

Customers are the most urgent stakeholder group for the selected company.

This research statement will be confirm based on the results of author's research and identified Stakeholder Profile developed based on the Stakeholder Circle Methodology.

Author identified the initial list of stakeholders for author's research based on the content analysis and literature search. Respondents were asked to identify and prioritize 10 most important stakeholder groups. The initial list of stakeholders follows:

1. Banks
2. Competitors
3. Customers
4. Educational institutions
5. Employees
6. Government
7. Management
8. Media
9. Suppliers
10. Transporters

Results and Discussion

Respondents identified the key stakeholder groups of the selected university and evaluate the following characteristics for each stakeholder group – for detail see table 2.

Table 2: Basic information

Stakeholder group	Direction	Internal / external	Importance	Mutuality	Classification
Customers	outwards	E	Interest, impact, power to affect failure of the company	Customer satisfaction	Customer
Competitors	sidewards	E	Impact, interest	-	Other
Media	outwards	E	Interest	Can influence views of the organisation	Community
Employees	downwards	I	Knowledge, power to affect success of the company	More work experience, more money	Team
Suppliers	outwards	E	Contribution, source of resources	-	Supplier
Management	upwards	I	Knowledge, influence, power to affect success of the company	Organisational power	Manager
Transporters	outwards	E	Contribution	-	Other
Banks	outwards	E	Influence, knowledge, power to affect success of the company	-	Authorities
Government	outwards	E	Influence, power to	-	Authorities

			affect success of the company		
Educational institutions	outwards	E	Interest	Career advancement	Community

As we can see from table 2 most of key ten stakeholder groups are external stakeholders. There are only two internal stakeholder groups among 10 most important stakeholder groups – employees and management. Both of them dispose of knowledge and power to influence the success of company. Management and employees have opposite direction upwards (management) and downwards (employees). Direction upwards defines the influence of management mainly top management over the company's activity and direction downwards denotes part as well as full time staff, specialist, team members working with management to achieve outcomes and goals of the company (Bourne, Walker 2008, Bourne, Kasperczyk 2009). Direction of influence upward refers to maintain and develop relationships and downwards is about the idea of managing a team of employees (Bourne 2008b). As can be seen from table 2 most of the stakeholder represents direction outwards that involves impacts of lots of external stakeholder groups – e.g. suppliers, transporters, government, banks, media, etc.

Application of the mutuality factor in the Stakeholder Circle Methodology and commonly in stakeholder management addresses the specific two-way nature of relationship between company and stakeholder groups. Mutuality combines both requirement of stakeholder from company and success of company's outcomes as well as the question why and how is stakeholder important for company (Bourne 2010).

Based on the previous steps respondents were asked to start to evaluate the other characteristics for complex stakeholder profile – power, proximity, value, action, urgency and priority. Evaluation of these characteristics is summarized in the following tables.

Table 3: Evaluation of power, proximity, value and action of stakeholder groups

Stakeholder group	**Power**	**Proximity**	**Value**	**Action**
Customers	high level to influence company	regular contact with company	Outcomes are important	significant effort to influence company
Competitors	high level to influence company	no direct contact with company	Limited or no stake in outcomes	probability to influence company
Media	high level to influence company	no direct contact with company	Limited or no stake in outcomes	significant effort to influence company
Employees	high level to influence company	direct proximity in company	Outcomes are important	significant effort to influence company
Suppliers	Low level	no direct contact with company	Small indirect stake in company	Stakeholder maybe prepared to influence outcomes
Management	high level to influence company	part-time working stakeholder groups	Very high stake in company	significant effort to influence company
Transporters	Low level	no direct contact with company	Limited or no stake in outcomes	No probability to attempt to influence company
Banks	high level to influence company	Regular contact	Outcomes are important to stakeholder as well as company	High probability and significant effort to influence company
Government	informal capacity to	regular contact with company	Medium direct stake in company	Stakeholder maybe prepared to influence

	cause change			outcomes
Educational institutions	Low level	no direct contact with company	Limited or no stake in outcomes	No probability to attempt to influence company

The table 3 summarizes main characteristics – power, proximity, value and action. The power of stakeholder group answers the question if the stakeholder group have limited or high power to influence. Stakeholder groups with high level of power may have stopped the activities or permanently change activities of the company. The table above shows that there are several stakeholder groups, which have the highest level of power that means high level to influence company or stopped company's activities. In this case stakeholder groups with the highest level of power are represented by banks, management, employees, customers, competitors and media. Proximity represents the closeness of stakeholder group to company (Bourne 2008b) and provides another way of identifying of stakeholder influence of the company (Bourne 2010).

In terms of proximity internal stakeholder groups – employees and management are directly involved in the activity of the selected company. Most of the stakeholders in the case of selected company have no direct contact with company. Stakeholder groups that are not directly involved in the activity of this company are competitors, media, suppliers, transporters and educational institutions. Banks, government and of course customers have a regular contact with the company.

Value is sometimes marked as vested stake and represents the stake of the stakeholder group in the company output. Customers, employees, management and banks have the highest stake in company outputs. On the other hand there are several stakeholder groups with limited or no stake in outcomes – competitors, media, transporters and education institutions. Action represents importance and expresses the probability of the action of stakeholder forward to influence the company. Customers, media, employees, and management represent stakeholder groups with very high importance of the company to stakeholder group therefor there could be a significant effort of stakeholder to influence outcomes of the company. High probability and effort to influence outcomes of the company was assigned to banks. The other stakeholder groups are connected with low probability to attempt to influence company or preparedness to attempt to influence outcomes. It is necessary to emphasize to the understanding and subsequent satisfaction of needs, wants and requirements of stakeholder groups that represents significant effort and high probability to influence outcomes of the company.

Evaluation of action and value entering into the last factor – urgency (for detail see table 3)

Table 4: Evaluation of urgency and prioritisation of stakeholder groups

Stakeholder group	**Urgency**	**Priority**
Customers	Urgent activities according to the common marketing communication	1
Competitors	Planned activities warranted within medium timeframe	2
Media	Planned activities warranted within medium timeframe	3
Employees	Urgent activities according to the common marketing communication	4
Suppliers	Planned activities warranted within medium timeframe	5
Management	Urgent activities according to the common marketing communication	6
Transporters	Little need of activity outside routine marketing communication	7
Banks	Planned activities warranted within short timeframe	8
Government	Planned activities warranted within medium timeframe	9
Educational institutions	Little need of activity outside routine marketing communication	10

The most urgent stakeholder groups of the selected company are customers, employees and management. The company should place particular emphasis on processing of marketing communication plan for these stakeholder groups. The company has to perform urgent activities according to the common marketing communication. The company should focus on planning activities in marketing communication within medium timeframe mainly for media, since this stakeholder group has the power to influence the perception of the other stakeholder groups of the company and company's brand perception, other stakeholder view of the company and opinion on the company, etc. Company should plan marketing communication activities in medium timeframe for competitors, suppliers and government, too. There is no or little need of activities outside routine marketing communication for transporters and educational institutions.

Since the stakeholder group with highest priority is customers and this stakeholder group is connected with urgent marketing communication activities, the selected company has to focus on targeted marketing communication with this stakeholder group. The results of the author's research confirm the research statement that customers are the most urgent stakeholder group for the selected company. Competitors and media follow customers with the respect of priority.

Conclusion

The essential starting point for developing of effective targeting communication is evaluation of all factors presented in this paper as well as understanding needs, wants, requirements and expectations of all key stakeholder groups. Therefore it is necessary to carried out detail content analysis to be able to meet these needs and expectations. Based on the author's research the most important and urgent stakeholder groups for marketing communication were identified. The research statement was confirmed and customers were identified as the most important stakeholder group with the highest priority. Customers are not only the most urgent stakeholder group, but customers have also power to stop (as Bourne state 'kill') the company's activity. This stakeholder group with outwards direction of influence has the similar influence and power as management of the company. Four most important stakeholder groups have high level of power to influence company outcomes, but only customers have regular contact with company and outcomes of the company are important for them.

Second highest priority was assigned to competitors and third highest priority was assigned to media. These stakeholder groups require only planned activities warranted within medium timeframe, have limited or no stake in outcomes of the company, but on the other hand they have the highest power, high level to influence company. The company has to start to communicate properly inside organization, as urgent activities in marketing communication for employees and management are needed. The internal stakeholder groups should not be omitted since as Fiala and Prokop state inter-organizational trust, that is based on the proper communication has statistically significant positive effect on the performance of the company (Fiala, Prokop, 2013).

After description of Stakeholder Profile in the Stakeholder Circle Methodology, the identification of Stakeholder Engagement Profile follows to assessing the stakeholder level of engagement. Targeted communication plan is developed based on the Stakeholder Engagement Profile. Stakeholder Circle Methodology uses Engagement index for evaluation of development of Stakeholder Engagement Profile over the time period. The further author's research will focus on the Stakeholder Engagement Profile and Stakeholder Index.

Improving Recommendations Using Context from Users' Reviews

Abstract

Recommender systems enable E-commerce websites to improve their sales by suggesting relevant items to customers. If considering the context of buying situations, more accurate recommendations can be computed. In this paper, we discuss the issue of using the contextual information contained in users' reviews in order to improve recommendation.

Keywords: Recommender systems, context aware recommender systems, users' reviews.

Introduction

In e-commerce websites, as in many other websites, there are often a huge number of online resources available to users. Most of the times, users are lost and cannot directly know, for example, what item to buy, or what online news to read, or even to which restaurant to go. Reaching relevant resource is not an easy task. Recommender Systems (RS) (Ricci et al., 2011) try to overcome this difficulty by suggesting to users items of their interest. Indeed, RS aim to filter items according to users' profiles and preferences. They thus, on one hand, help users find items they may want to buy, and in the other hand, help businesses generate more sales. To do this, RS aim to predict users' ratings by considering their previous ratings as well as information about users and items.

While traditional Recommender Systems focus only on users and items when computing predictions, Context Aware Recommender Systems (CARS) (Adomavicius and Tuzhilin, 2011), more sophisticated ones, aim to provide more accurate predictions by considering information describing the situation of buying. Indeed, some contextual information (such as time, weather or accompanying persons) may influence user decisions. For example, a same user may book different hotels in different situations: one for his business trip with Wi-Fi or meeting area, and a different one for his family holiday with accommodations like family rooms or even childcare services. Hence, the recommender system should not suggest the same hotel in both situations.

Getting contextual information is a first step for building a context aware recommender system. In e-commerce websites, such information is hardly ever explicitly provided by users. Moreover, most of current e-commerce web sites allow users, not only to rate items, but also to write reviews on these items. While the primary goal of these reviews is to express sentiments and preferences about items, they often carry some contextual information.

In this paper we introduce first CARS and its main issues. After that, we discuss works on getting contextual information from users' reviews. In the third section, we present some remaining open question. The last section concludes the paper.

Context Aware Recommender Systems

The key idea of CARS is to consider, in addition to users and items, extra information related to the context in order to provide more accurate predictions. To do that, a CARS's designer should answer to the main questions: (i) how to get the contextual data? (ii) From the contextual data, which ones

are relevant for the recommendation purpose? (iii) And how to introduce the contextual data in the recommendation process. In this section, we introduce these main issues of CARS.

Getting Contextual Data for Recommendation

A first step to provide context aware recommendation is to obtain the contextual data. To do this, Adomavicius et al. (Adomavicius and Tuzhilin, 2011) listed three different approaches: (i) Explicitly, by asking direct questions to relevant people or eliciting this data through other means; (ii) Implicitly, from the data or the environment; for example, temporal information can be extracted from the timestamp of a transaction, and information about user localization can be detected by a mobile telephone company. This approach is common on mobile context aware application as most current mobile devices are equipped with sensors that inform about users' current context. (iii) By inference, using statistical or data mining methods. As examples, authors of (Palmisano et al., 2008)[3] explored the possibility of inferring the contextual information 'intent of purchase' from the existing customers' demographic and transactional data. They demonstrated that it is possible to infer fairly accurately the context on condition that a proper segmentation level is identified, and good predictive model is selected. In other works (Lahlou et al., 2013c) (Lahlou et al., 2013a) (Lahlou et al., 2013b), researchers aimed to infer the contextual information 'intent of purchase' from users' reviews. This last point is studied in more details in the next section.

Selecting Relevant Contextual Data

Another issue in CARS is determining which contextual information is relevant and which is not. This is an important issue since it allows to minimize the risk to set up an expensive process in order to collect ratings under some contextual conditions and discover a posteriori that these selected conditions were irrelevant or not important to investigate (Baltrunas et al., 2012). Furthermore, selecting relevant data could improve recommendation accuracy(Vargas-Govea et al., 2011).

Paradigms for Incorporating Context into Recommendation Computations

Once relevant contextual attributes are obtained, the next step is the incorporation of these new data in the recommendation computation.

In traditional recommender system, the goal is to compute a utility function that affects a score for each pair (user, item). This score represent the predicted rating for the user on this item. In contrast, the goal in CARS is to predict a score for the triplet (user, item, context). Adomavicius et al. (Adomavicius and Tuzhilin, 2011) described three paradigms to incorporate the contextual information into the recommendation algorithm: (i) the contextual pre-filtering: where contextual information are used to only select the relevant set of data, and then recommendations are computed using any traditional recommender system on the selected data; (ii) the contextual post-filtering: where contextual information are initially ignored, and recommendations are computed using the entire data. After that, the contextual information are used to adjust resulting recommendations for each user; (iii) the contextual modeling, where contextual information are used directly in the modeling technique in order to provide predictions.

Inferring Context from Users' Reviews for Context Aware Recommendation

Suggesting to buyers more relevant items need to know more about the context of their buying situations. For instance, users' decisions may be affected by their intents of purchase. However, asking them to directly fill in such information may be a heavy task. Moreover, current e-commerce web sites allow users to write reviews on the purchased items. As aforementioned, though these reviews are primarily written to express sentiments and preferences about items, they often carry some contextual information. Figure 1 shows a review containing some contextual information. As

one can see, the review in figure 1 reveals who was accompanying the reviewer, the purpose of his trip, the duration and the date of his stay.

I stayed at this hotel with two colleagues on a business trip for 7 nights in December of 2007. I have stayed in many hotels across the world and hotel Maamoura ranks among the top of my hotel experiences. The staff is incredibly friendly and helpful. The rooms are very spacious, clean, well furnished and quiet. The bathrooms are great as well. The hotel location is excellent in the middle of the city but on a quiet side street. There are tons of bank machines, pay phones and food options nearby. The hotel has 2 elevators. After long days of work I often found myself staying up to talk to the hotel manager simply because he is a really great guy. You will also be hard pressed to find a hotel manager who is more proud of Morocco and more dedicated to ensuring that everything goes well for you on your trip. I will definitely stay there again upon a return trip to Casablanca.

Fig.1: A hotel review that contains some contextual information

Recent works tackle the issue of inferring contextual information from reviews in order to use it for CARS. To do that, authors in (Lahlou et al., 2013c) (Lahlou et al., 2013a) (Lahlou et al., 2013b) used a text classification approach where target categories are the set of possible values that can take the contextual information. For example, they classify hotel reviews into the following category in order to know the "Trip type": "Business", "Couple", "Family", "Friends" and "Solo". They use and compare different classification algorithms with different settings. Their experiments show that the Multinomial Naïve Bayes (MNB) algorithm outperforms Support Vector Machine (SVM), k-Nearest Neighbor (k-NN) and Decision Trees (DT) for this task. They achieve promising results given all encountered challenges.

In another work, (Aciar, 2010) identifies contextual sentences in users' reviews by applying text mining tools to define rule set. He classify contextual sentences as either 'contextual' (that contain information about the context) , or 'preferences' (that contain preferences about features that users have evaluated). Similarly, in (Bauman and Tuzhilin, 2014) researchers start by classifying reviews in two categories depending on if they contain contextual information, that they call *specific*, or not, that they call *generic* . After that, they capture contextual words from specific reviews using word-based and a Latent Drichlet Allocation (LDA) based methods.

Other works, (Hariri et al., 2011) (Li et al., 2010) investigate others text mining techniques to detect contextual information from reviews. (Hariri et al., 2011) use a Labeled Latent Drichlet Allocation (L-LDA) as a text categorization technique in order to infer the context, whereas (Li et al., 2010) evaluate and compare three classifiers for this task: a rule based classifier, Maximum Entropy, and a hybrid classification algorithm.

Open Perspectives

Once contextual information are correctly inferred from online reviews, the following step is to incorporate it into recommendation computations. Obviously, each inferred contextual information has a certain score of accuracy. One open issue is to find the optimal way to efficiently incorporate this contextual information while considering their uncertainty.

Furthermore, using reviews for CARS can be used in a new different way. Instead of inferring contextual information from reviews, once can consider all the review as the context. Then this context can be used for recommendation. A way to do that may be applying text mining techniques in order to transform the text into 'bag of words'. Then, each word from a review would have a score indicating its importance in the review. Note that the number of contextual feature would be very large. A feature selection step would be unavoidable to filter relevant words that would be the context. CARS algorithms may be then applied.

Conclusion

Users' reviews contain multitude of information that can help to provide more accurate recommendations and therefore improve sales in e-commerce websites. In this paper, we discussed the issue of using available users' reviews in order to get contextual information about the buying situation in order to use it to improve recommendation. Although some works tried to get context from reviews, this promising topic remains open and still needs deeper investigations.

Creativity, Ambidextrous Leadership and Innovative Performance: A Multi-Level Conceptual Framework

Katarzyna Piórkowska, Wroclaw University of Economics, Wroclaw, Poland,
katarzyna.piorkowska@ue.wroc.pl

Abstract

The creativity phenomenon might be considered as either an outcome (novel and useful on the basis of originality, fluency, and flexibility) or a process (cognitive and behavioural). Moreover, creativity is encompassed in ambidextrous leadership in terms of creative and divergent thinking as well as leader's exploitation and exploration behaviour. The aim of the paper is to develop a conceptual framework regarding the relationships between creativity, ambidextrous leadership and innovative performance incorporating a multi-level perspective. The aim of the paper has been achieved through critical literature studies. The key findings constitute the following propositions: (1) Individual, team, and organizational creativity with their antecedents are positively associated with subjective and objective innovative performance as well as this relationship is mediated with both cognitive divergence/convergence and exploration/exploitation behaviour; (2) Ambidextrous leadership permeates creativity at every methodological level (individual, team, and organizational) and is reflected with divergent and convergent thinking styles in terms of a process, an outcome, and context; (3) Cognitive divergence is positively associated with creativity that in turn leads to exploration behaviour; (4) Cognitive convergence is positively associated with rigidity that in turn leads to exploitation behaviour; (5) Leaders' temporal flexibility moderates the associations between cognitive divergence and creativity as well as cognitive convergence and rigidity respectively; (6) Exploration behaviour is positively associated with both subjective and objective innovative performance; (7) Exploitation behaviour moderates the relationship between exploration behaviour and subjective & objective innovative performance; (8) Subjective innovative performance might moderate the relationship between exploration behaviour and objective innovative performance.

Keywords: leaders' creativity, leadership, innovative performance, ambidexterity.

Introduction

The creativity realm emerged strongly from works of Wallas (1926), Guilford (1950) and Torrance (1962, 1974). Creativity has been agreed to be a contributor towards inter alia performance, innovative performance, competiveness, and entrepreneurship (e.g. Anderson et al., 2014; Mumford and Gustafon, 1988) at the individual, team, organizational, cultural, and even societal level (a systems view) (e.g. Anderson et al., 2014; George, 2007; Hennessey and Amabile, 2010; Shalley et al., 2004). The creativity phenomenon might be considered as either an outcome (novel and useful on the basis of originality, fluency, and flexibility) or a process (cognitive and behavioural). Admittedly, creativity is encompassed in ambidextrous leadership in terms of creative and divergent thinking as well as leaders' exploitation and exploration behaviour (e.g. Zacher, Robinson and Rosing, 2014).

While much research has been conducted in the realm of creativity, innovation as well as leadership, there is no evidence in terms of the associations between ambidextrous leadership, creativity, and innovative performance at different levels of analysis. Hence, the aim of the paper is to contribute to that gap and to develop a conceptual framework with regard to the relationships between creativity, ambidextrous leadership and innovative performance incorporating a multi-level perspective. The aim has been achieved through critical literature studies.

Insights on creativity phenomenon

A large body of research has been performed to better explain and understand that phenomenon as well as it has been explored from various perspectives, e.g. cognitive, neurological, personal, or organizational (Hennessey and Amabile, 2010) as well as in terms of different theoretical approaches (e.g. psychological trait theory, behavioural theories & functionalist approaches, and Social Cognitive Theory & socio-constructivist approaches (Edwards-Schachter et al., 2015). Creativity as the ability to generate and extend ideas, concepts, and methods in novel ways (Csikszentmihalyi, 1988) is a multidimensional and disentangling construct considered in terms of an individual with traits, a process, and an outcome. Admittedly, in a line with a propulsion theory (Sternberg, 1999; Sternberg, 2006; Sternberg, Kaufman and Pretz, 2001, 2002), creativity can be of different kinds, depending on how it propels existing ideas forward ranging from minor replications to major redirections in thinking. The creative process is conceptualized as a form of action (a socio-cultural act) by which individuals move between different positions constructing new perspectives with reflexivity and emergence of novelty (Glaveanu, 2015) that constitutes an outcome of a creative process.

With regard to antecedents and determinants of individual creativity, the following ones attracted much scholars' attention: cognition, emotion, motivation, personality traits, environment (context). For instance, according to the investment theory (Sternberg, 2006; Sternberg and Lubart, 1991, 1995), creativity requires a confluence of six distinct but interrelated resources: intellectual abilities (synthetic, analytic, and practical-contextual skills), knowledge, thinking styles (a legislative style), personality, motivation, and environment. Cognitive individual differences reveal in divergent and convergent creativity (Eysenck, 2003; Runco, 2007; Soroa et al., 2015; Tan and Wong, 2015). It involves a dynamic perspective of creativity comprehended as an interaction between thinking styles, affective dispositions, and motivational preferences (Bledow, Rosing, and Frese, 2013). Consequently, bipolar cognition dimensions have been recognized: rule-oriented cognitive strategies and set-breaking cognitive strategies (Soroa et al., 2015). Regarding emotion, two dominant dimensions have been recognized as critically salient: positive affect (mood) and negative one (De Dreu, Baas and Nijstad, 2008; Russell and Carroll, 1999). With regard to motivation as the factor influencing creativity, approach orientation (divided into proactive and preventive) has been evidenced as relevant in enhancing creativity (Higgins, 1997, 2014). Hence, goal orientation has been proposed as a moderator of the effects of mood on creativity (De Dreu, Baas and Nijstad, 2008; Roskes, De Dreu and Nijstad, 2012). Moreover, intrinsic, task-focused motivation is essential to creativity (Sternberg, 2006) and is determined by internal locus of control (Dewett, 2004). In accordance with personality, Sternberg and Lubart (1991, 1995) have supported the salience of inter alia the following personality attributes for creative functioning: willingness to overcome obstacles, willingness to take sensible risks, willingness to tolerate ambiguity, and self-efficacy. Although most studies on creativity are concentrated on the attributes of creativity, the context illustrating an interaction between individuals and context (environmental conditions) ought to be also taken into account (Runco, 2004; Sternberg, 2006). Regarding team level creativity, the following antecedents have been recognized by scholars: characteristics of a team, the integration process, coordination, flow information (Fischer, Oget and Cavallucci, 2015; cf. Bouchard and Bos, 2006). When it comes to the antecedents of organizational level creativity, the characteristics of an organization are very salient (Fischer, Oget and Cavallucci, 2015; cf. Bouchard and Bos, 2006).

Creativity and innovation as well as ambidextrous leadership - rationale

Creativity constitutes the starting point (impetus) for innovation (Massaro, Bardy and Pitts, 2012; Woodman, Sawyer and Griffin, 1993; Zacher, Robinson and Rosing. 2014). Innovation constitutes the implementation of creative ideas within an organization (Turkson and Appiah, 2009). Roberts (1988) divided innovation into two stages: invention (the generation of novel ideas) and exploitation (implementation of these ideas in the sense of value innovation). In a similar vein, scholars make explicit

distinction and identify the first stage of innovation with creativity (Bledow et al., 2009; Cropley, Kaufman and Cropley, 2011; West, 2002), however, it might be also envisaged that both creativity and innovation processes overlap and constitute iterative cycles (Haner, 2005) leading to outcomes of innovation - innovative performance (subjective and objective).

Leadership has been recognized as one of the predictors of creativity and innovation (e.g. Williams and Foti, 2011; Zacher and Johnson, 2014; Zacher, Robinson and Rosing, 2014; Zhou and Hoever, 2014). The ambidexterity leadership theory for innovation proposes that leaders reflect opening and closing behaviour positively predicting exploration (experimenting, making challenging assumptions) and exploitation behaviour (adhering to standards, avoiding risks, focusing on goal achievement) respectively (Zacher, Robinson and Rosing, 2014). It also posits that innovative performance is the highest when both exploration and exploitation behaviour are high. Moreover, ambidexterity is an important antecedent of innovation at the individual, team, and organizational level and all levels participants have to manage the tension between exploration and exploitation to be innovative (Bledow et al., 2009; Gibson and Birkinshaw, 2004; Zacher, Robinson and Rosing, 2014)

Creativity, ambidextrous leadership and innovative performance – a multi-level research perspective

The creativity construct involves multiple ontological, epistemological, and methodological associations (e.g. Batey, 2012; Bouchard and Bos, 2006; Fischer, Oget and Cavallucci, 2015). Epistemologically, it concerns individuals, teams, organizations as well as culture and society – creativity ought not be only analysed at the individual level, yet it should involve collaboration relationships among members of a team (Kind and Kind, 2007) (e.g. particular teams, top management teams). Ontologically, it might cover at least traits, processes, and outcomes. With regard to the methodology, both quantitative and qualitative approaches and measures are alluded. It is convergent with invariants set out by Fischer, Oget and Cavallucci (2015) that reflect various levels of creativity constructs: the originality of imagination and the concept of transgression, the interdependence of participants, and dependence on cultural, social, and disciplinary contexts. Leadership with its ambidextrous rationale is encompassed in every level and facet of creativity and innovative performance evaluated both subjectively and objectively. The proposed conceptual framework is presented in Figure 1.

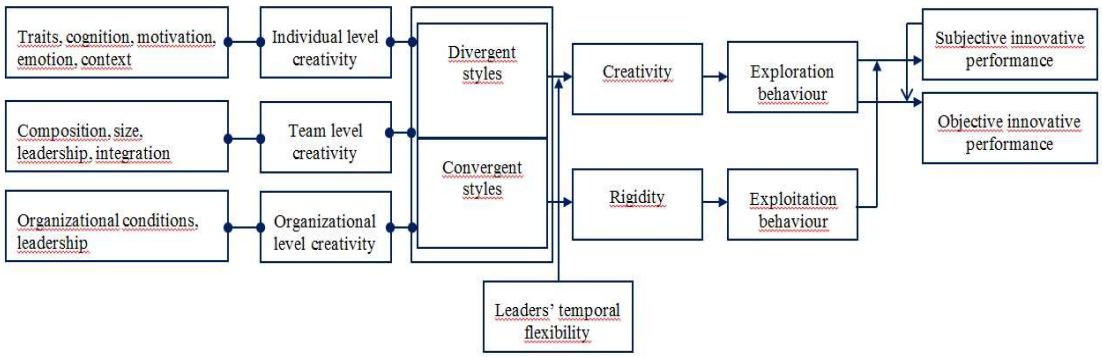

Fig. 1: A conceptual framework of creativity, ambidextrous leadership and innovative performance

As well as this, the following primary propositions have been formulated:

Proposition 1: Individual, team, and organizational creativity with their antecedents are positively associated with subjective and objective innovative performance as well as this relationship is mediated with both cognitive divergence/convergence and exploration/exploitation behaviour. Hence,

Proposition 2: Ambidextrous leadership permeates creativity at every epistemological level (individual, team <including top management teams>, and organizational) and is reflected with divergent and convergent thinking styles in terms of both a process and an outcome.

Proposition 3: Cognitive divergence is positively associated with creativity that in turn leads to exploration behaviour.

Proposition 4: Cognitive convergence is positively associated with rigidity that in turn leads to exploitation behaviour.

Proposition 5: Leaders' temporal flexibility moderates the associations between divergence and creativity as well as convergence and rigidity respectively.

Proposition 6: Exploration behaviour is positively associated with both subjective and objective innovative performance.

Proposition 7: Exploitation behaviour moderates the relationship between exploration behaviour and subjective & objective innovative performance.

Proposition 8: Subjective innovative performance might moderate the relationship between exploration behaviour and objective innovative performance.

Conclusion

The paper introduces, develops, and illustrates a conceptual framework with regard to the relationships between creativity, ambidextrous leadership and innovative performance incorporating a multi-level perspective drawing on current developments within those realms. Nonetheless, the contribution requires further investigation. First, methodology and measures for all particular constructs ought to be established. Second, it is necessary to specify innovative performance at every epistemological level. Third, detailed associations between individual, team, organizational creativity and their antecedents are going to be specified. Those complements will enable to develop hypotheses and conduct empirical research.

Acknowledgment

The paper is realized in the scope of the project that has been financed by the National Scientific Centre in Poland on the basis of the decision no. DEC-2012/05/D/HS4/01317.

Abstract

The present research aims to highlight the seriousness of plagiarism amongst postgraduate students of Cyprus Universities. It explores the students' perceptions of plagiarism as well as the reasons of plagiarism from the students' point of view. A total of 1128 postgraduate students participated in this study. A questionnaire survey was used for collection of primary data. Major findings revealed that almost three quarters of postgraduate students believe that copying is a very serious or serious problem; while approximately half of them believe that the item 'having a friend/a colleague do the work for them' is a very serious or serious offence. Half of the students have admitted that they have intentionally plagiarized written materials and 18.7% of them have courageously admitted that they have paid someone to do his/her work. Findings have also revealed that plagiarism is happening frequently amongst students. Lack of time to complete assignment was seen to be the most probable reason for plagiarism. This paper offers some recommendations to combat plagiarism. These recommendations include raising awareness, clarifying the rules of disclosure, using plagiarism-detection software, and creating a strong culture that promotes academic integrity.

Keywords: academic integrity, plagiarism, postgraduate students

1. Introduction

Northern Cyprus becomes a hub for the students from many different nationalities and cultures. The eight universities of Northern Cyprus are confronted with various challenges. One of these pressing issues is students' plagiarism. Soon as students register for their postgraduate courses, their professors require that they write articles about related topics of their study programs. The professors, then, state their main concern that students produce their work free from plagiarism. Putting this concern on top of professors' agenda implies that they have passed through terrible times facing the issue of students' plagiarism. If not, they are trying to give their fair share to the ongoing fight of this phenomenon.

The responsibility of the researcher is to be honest in his academic endeavors, and to conduct his/her researches considering all academic, honest practices. Violations of the academic honesty and integrity corrupt the proper advancement of knowledge. However, various studies have shown that plagiarism and other academic misconducts are happening. Thus the research can be seen as a natural response to an ongoing issue of great importance. It is also beneficial to study this issue in multicultural universities where students from so many different nationalities are taking part in the learning/teaching process.

However, the present study will not provide definitive answers and solution to plagiarism. Its general aim is to open the conversation around this academic misconduct.

The study is mainly conducted on postgraduate students of Northern Cyprus Universities in order to investigate their perceptions of plagiarism. It is assumed that students from different cultural background have different perceptions towards plagiarism. The research will also highlight the reasons of plagiarism from the students' point of view.

It is known that universities develop different instructional measures to discourage plagiarism, but it is also important to encourage approaches of developing strategies aiming at developing the students' attitudes and perceptions towards plagiarism. The present research argues that there is noticeably insufficient amount of research investigating the perceptions of students towards plagiarism in Northern Cyprus universities. Overall, the findings of the research will be used to determine how the students, professors and university managements can work together to develop a more honest and coherent teaching/learning environment for the better future of education.

2. Literature Review

According to www.merriam-webster.com, plagiarism is defined as "to use the words or ideas of another person as if they were your own words or ideas." Whereas online Merriam Webster Dictionary states that plagiarism was first used in 1716, dictionary.reference.com states that it was first used in 1615 and defines it as "an act or instance of using or closely imitating the language and thoughts of another author without authorization and the representation of that author's work as one's own." Regardless of the debate of the start of use, both dictionaries almost share the same definition. Moulton and Robinson (2002: 1316) define plagiarism as "appropriating someone else's words or ideas without acknowledgement."

Honig and Bedi (2012: 119) state that "Failing to act as a profession immediately and assertively in the face of these recurrent ethical transgressions threatens the very essence of our community of knowledge." As it is considered to be one of the dishonest practices in academia, plagiarism puts at risk the university degree value. It raises questions about the reliability of the teaching system as a whole. Causes of plagiarism have been studies by many researchers and scholars. Hansen and Anderson (2015: 427) concludes that what challenges the meaning of plagiarism are the low rate of understanding of plagiarizing university students, the emergence of plagiarism-related e-commerce and dealing with students as customers not leaners.

A number of studies tried to examine the nature of plagiarism and the reasons for this academic dishonesty. Lines (2015) examined the motivations and nature of substantive editing among postgraduate students in Australia. The study discussed the problem of misunderstanding the dividing line between professional editing and substantive editing. It is found that there were lots of students engaging in this type of plagiarism. Findings showed that there are certain negative effects of this problem. Kumari and Lakshmi (2015) described in their study different concepts of plagiarism like types of citations, recognition of plagiarism and obstacles facing students while writing their theses. They also suggested some steps to be taken to avoid this critical problem which faces the academic life. Bahadori et al. (2012) reviewed some of scientific texts related to plagiarism. Their main aim was to enhance the understanding of teachers and students of plagiarism through providing a coherent understanding of the roots and factors of this phenomenon. Ramzan et al. (2012) conducted a research to examine the level of awareness and the seriousness of plagiarism among graduate and postgraduate students of Pakistan. Findings showed that there was a low level of awareness amongst student towards plagiarism. It was also noticed that most of students did not understand the meaning of plagiarism. Interestingly, a substantial number of students said that they intentionally plagiarized some written materials.

Different studies aimed to show the relevance between theory and practice of academic integrity. James and Mahmud (2014) analyzed the opinions of 28 academic integrity interviewees. The main target group specifically was 12 persons who were affiliated in legal departments. It was found that legal students

breached the academic integrity despite their understanding of its negative effects on their professional life. Gallant and Drinan (2008) tried to bridge a gap between theory and practice in the academic integrity activity, to examine the current notions of leadership role in fighting research misconduct, and to suggest new ways to evaluate the relationship between the research and teaching goals. The paper introduced a complete case study to show how a proposed model can be used by postsecondary institutions to fight academic misconduct.

Some other studies examined the frequency and size of this phenomenon. Graig and Dalton (2014) studied the perceptions of Abu Dhabi Petroleum Institute's first-year students towards the frequency and proportion of cheating and it studied the reasons for such behavior. Findings revealed that frequency of cheating differed from one semester to another. The frequency decreased as the students spent more time at the university. The researcher called for developing an honest inquiry system so as to overcome the plagiarism problem and simplify the students' engagement and ownership of their academic work. Honig and Bedi (2012) conducted an exploratory study for a number of papers which were presented at a conference. They examined 279 papers to check them for plagiarism. Findings showed that 25% of the papers had some amount of plagiarism and 13% of them had significant plagiarism. It was noticed that the monitoring system of academic activities was not appropriate among the Academy of Management members.

Another group of studies also examined the reasons for plagiarism, ways of preventing it, and students' perception about plagiarism. Mohammed et al. (2015) reviewed about five hundred articles covering various aspects of plagiarism. They found that the main reason for plagiarism is lack of knowledge about it. Among the reasons were also found the limited period or the constraint of time for conducting the research, unskilled writers and researchers, and the continuous pressure of publishing works in well-known journals. The study also explained how submitted manuscripts are being checked for plagiarism using software and other related technological services. The study concluded that the basis of preventing this problem is raising awareness. Rezanejad and Rezaei (2013) examined the awareness, reasons, attitudes towards instructors, and perceptions of Iranian language students about plagiarism. The students have shown different opinions about definition of plagiarism. Most of the students viewed plagiarism as using words of others as if they are their own. Results indicated that students regard copying assignments completely from other friends as a dishonest act. It was also found that students argued that instructors guess about students who might have committed this dishonest act rather than check about students who have really committed it. It was noticed that most of Iranian students regard easiness of plagiarism as the most influential reason for plagiarism. Findings also showed that university professors played a crucial role in teaching students about plagiarism

Northern Cyprus Universities offer a number of postgraduate programs in a number of fields of studies including but not limited to natural and applied sciences, social sciences and fine arts. Most of the programs are taught in English. Others are taught in Turkish. A great number of postgraduate students are non-native speakers of English language. There are some students who are fluent in English and others who have excellent command of it. Different expressions of concerns exist for the study of plagiarism. The researchers want to open this discussion by studying the perceptions and reasons for this academic misconduct problem.

3. Methodology

The objective of the study is to examine postgraduate students' perceptions of plagiarism as well as the reasons they believe to cause this academic misconduct in Northern Cyprus Universities. To achieve the objective of the study, a questionnaire consisting of five sections was used as the main tool of data collection.

In total, 1500 questionnaires were distributed. The questionnaires were collected directly. The researchers received back 1128 questionnaires out of the 1500 questionnaires that were distributed, which represent 75.2% of total surveyed sample.

Once the data collection was finished, the responses were analyzed using the Statistical Package of Social Science (SPSS). The reliability of the questionnaire was measured by Cronbach's Alpha coefficient. Another tool used for the analysis was Factor analysis in order to describe the correlated variables and variability among observation. Frequencies were also used.

4. Ethical Consideration and Limitations of the Study:

In conducting this study, the researchers acknowledged some ethical considerations. The information collected was treated with strict confidentiality and used for the purpose of the study only. Also, the questionnaire used for this study was originally developed by Graig and Dalton (2014) who conducted an almost similar study in the Petroleum Institute, Abu Dhabi, United Arab Emirates. However, the researchers of the current study neglected the first section of the original questionnaire which aimed to discover the students' awareness and understanding of institutional policy which is not a concern for this study. Instead, they changed this section and sought to get some demographic data about the respondents. The content of the other four sections of the original questionnaire was almost kept. One item was added to the third section of the questionnaire so as to guarantee the consistency between the second, third and fourth sections in the questionnaire. The shape was slightly modified to simplify answering the statements.

The study also has some limitations. It addresses the issue from the student's point of view. There are other factors or players who may have different opinions concerning this pressing phenomenon. Another limitation of the study is that it is applied only on postgraduate students and it does not include the undergraduate students who may have different points of views regarding plagiarism, or may see the reasons for plagiarism differently.

5. Results

5.1 Demographic Statistics

The data showed that 73.6% of the respondents were males, while 26.4% of them were females. It also showed that 81.7% of the respondents were MA students, while 18.3% of them were PhD students. Table 1 shows the frequency and percentages of the demographic variables.

Table 1: Sample Distribution of Demographic Variables

Variables		**Frequency**	**Percentage**
Gender	Male	830	73.6%
	Female	298	26.4%
	Total	**1128**	**100%**
Educational Level	Master	921	81.7%
	PhD	206	18.3%
	Total	**1128**	**100%**

5.2 Factor Analysis

Bartlett's Test was employed for the first group of questions which were related to general perceptions of the seriousness of offence. It is found that the approx. Chi-Square is 606.774, the Degree of Freedom is 28.00, and significance is 0.000. Findings show that the value of the Kaiser-Meyer-Olkin Measure of Sampling Adequacy (KMO) is 0.878. This result shows that the data were adequate for Factor analysis.

Bartlett's Test was also used for the second group of questions which were related to engagement in the behavior of offence. It is found that the approx. Chi-Square is 522.919, Degree of Freedom is 28.00, and significance is 0.000. Results show that the value of Kaiser-Meyer-Olkin Measure of Sampling Adequacy (KMO) is 0.832. This result also shows that the data were adequate for Factor analysis.

Bartlett's Test was also employed for the third group of questions which were related to frequency of occurrence of offence. It is found that the approx. Chi-Square is 850.923, Degree of Freedom is 28.00, and significance is 0.000. Findings show that the value of Kaiser-Meyer-Olkin Measure of Sampling Adequacy (KMO) is 0.918. This finding shows that the data were adequate for factor analysis.

Bartlett's Test was finally employed for the fourth group of questions which were related to reasons for academic dishonesty. It is found that the approx. Chi-Square is 384.992, Degree of Freedom is 66.00, and significance is 0.000. Findings show that the value of Kaiser-Meyer-Olkin Measure of Sampling Adequacy (KMO) is 0.771. This finding shows that the data were adequate for factor analysis. Twelve Factors have been extracted. Out of them one Factor has been excluded due to the value of Factor loading which was less than 0.5.

According to Factor Analysis table, all the variables are well fitted in factor solution. This is because most of the factors have loading value more than 0.50 except one Factor in the group questions of reasons for academic dishonesty. The result of factor analysis gives evidence to the proper use of the instrument which measures the variables of perceptions and reasons of plagiarism, and allows proceeding for data collection. The reliability was tested by performing the Cronbach's Alpha reliability statistics. Results indicate the high reliability of the present measure. Factor Analysis table shows that the determinant is more than 0.00001. This indicates the absence of multicollinearity. Appendix 1 shows the Factor Analysis results.

5.2 Perceptions

5.3.1 General Perceptions of the Seriousness of Offence

Concerning the results of the students' general perceptions of the seriousness of plagiarism, analysis has shown that 74% of the postgraduate students believe that 'copying from notes in an exam/test/quiz' is very serious or serious. The other ranking and percentages of the seriousness of offence as perceived by students are found to be as follows: 71.2% for copying a colleagues answer in an exam/test/quiz, 70.7% for plagiarizing work from others and passing it off as their own, 70.2% for copying a homework assignment from a peer, 65.9% for providing answers to a friend/colleague in an exam/test/quiz , 57.3% for paying someone to do the assignment, 54.4% for doing homework for a friend/colleague, and 52.9% for having a friend/a colleague do the work for them.

5.3.2 Engagement in the Behavior

Concerning the results of the students' frequency of engagement in the behavior of plagiarism, analysis has shown that 49.5% of the postgraduate students have plagiarized work from others and passed it off as their own, 43.3% have done homework for a friend/colleague, 41.9% have allowed a friend/colleague to copy his/her work, 40.9% have provided answers to a friend/colleague in an exam/test/quiz, 37% have copied homework assignment from a peer, 27.9% have copied a colleagues answer in an exam/test/quiz, 25% have copied from notes in an exam/test/quiz, and 18.7% have paid someone to do his/her work.

5.3.3 Frequency of Occurrence

Concerning the results of the students' perceptions of the general frequency of occurrence, analysis has shown that 54.3% of the postgraduate students believe in the frequent or sometimes occurrence of copying a homework assignment from a peer occurs. Percentages and ranking for the other items of consideration are found to be as follows: 50% for providing answers to a friend/colleague in an exam/test/quiz , 47.6% for plagiarizing work from others and passing it off as their own , 46.7% for doing homework for a friend/colleague, 44.7% for copying a colleagues answer in an exam/test/quiz, 41.4% for copying from notes in an exam/test/quiz, 39.4% for having a friend a colleague do the work for them, and 38.4% for paying someone to do the assignment

5.3 Reasons

According to the findings of the research, 71.6% of postgraduate students believe that the most likely reason for plagiarism is lack of time to complete assignment. The other most probable reasons and percentages are found to be as follows: 62% for lack of interest, 61.5% for worth the risk to get a better grade , 61.1% for English not good enough, 60.6% for lack of understanding of how to complete assignment, 60.6% for authors' words are best, 60.1% for low chance of being caught or reported, 58.2% for penalties are minimal, 55.3% for too much effort required to paraphrase and quote, 52.9% for normal behavior (everyone does it/not considered serious), 52.9% for never been taught how to paraphrase and quote, 33.2% for taught to copy in school.

6. Discussion

A considerable number of students still do not understand the seriousness of the academic misconduct. Their level of awareness is still far away from expected. These findings of the research are almost consistent with the findings of other researchers conducted over the previous years (Ramzan et al., 2012; Graig and Dalton, 2014; Honig and Bedi, 2012; Rezanejad and Rezaei, 2013). However, it is surprising to find out that approximately half of the students tend to believe that giving their academic work to be done by their friends and colleagues is not a serious offence to academic integrity. This might be attributed to the concept of collectivism as it was introduced by Hofstede (1980). Students tend to take care and work of each other. From a collectivistic perspective, this manifested itself in the academic life. This goes in contrast to the individualistic perspective where students prefer to work independently. Other reasons for this high percentage may be attributed to the lack of time to complete assignment, lack of understanding of how to complete assignment, weak proficiency in English, or the behavior that everyone does it. A few variations in the percentages take place when the students were asked about the frequent occurrences of these items of consideration. This is just a confirmation of their original perception about the seriousness of the issue. The percentages dropped a little bit when students where asked if they themselves committed this academic misconduct. This is a natural response because everyone tends to believe in his right mind
Despite the students' moderate understanding of the seriousness of some of the offences, they have confessed to breach academic integrity. Though 70.7% of the respondents believe that plagiarizing work from others and passing it off as their own is a very serious or serious offence, 49.5% of them have courageously admitted that they have plagiarized and 47.6% of them have seen that this offence occurs frequently. First, this is again another place to tell that there is a low level of understanding about plagiarism because 29.3% still believe that plagiarizing work from others is not a serious offence. Second, the courage of confession may refer to the reasons of low chance of being caught or reported, minimal penalties, or taking the risk to get a better grade. Another area of breaching is found to be in the item of paying someone to do the assignment. When asked about their engagement in the offence, only 18.7% of the students admitted their frequent engagement. The percentage increased to 38.4% when students where asked about the general frequency of occurrence by others. This is also a natural psychological trend of believing in one's right mind. These results of breaching are consistent with the findings of other researches (Lines, 2015; Ramzan et al., 2012; James and Mahmud, 2014; Graig and Dalton, 2014).

Concerning the reasons for academic misconduct, the major findings are also consistent with the findings of other researches (Mohammed et al., 2015; Graig and Dalton, 2014; Rezanejad and Rezaei, 2013). The most probable reason for plagiarism is lack of time to complete assignments. This might be attributed to the balance students often try to make between different academic, social, professional or pre-professional, and psychological goals. Students may sometimes lose motivation for academic work. However, it is the responsibility of university lecturers to maintain the students' motivation by considering these goals in structuring their courses. Besides, lack of time is also associated with the lack of English language skills especially for students who come from non-speaking English communities. The problem may also have its roots in the lack of basic organizational skills including but not limited to time management techniques and keeping calendars. This results in low productivity and bad study habits.

Lack of interest is ranked second in the most likely reasons for plagiarism occurrence. Students need to be reminded of the importance of their studies and work assignments. Students also need not to believe that their assignments are busy work. The cause for this may be due to the students' belief that their lecturers don't read their work carefully. As a result, they do not work because they think that the assignments they prepare will not be recognized by their instructors. Instructors may impose their research agenda on the students. Giving the opportunity for students to select their own titles may add an incentive to them and encourage them to do good researches and projects. The third reason for plagiarism as perceived by students is worth the risk to get a better grade. Generally students want to maintain a high GPA. They see this as part of their success in life, so they express their concern for cheating and plagiarism to compete with their peers and colleagues. They cheat because they do not have a high level of confidence of themselves. They may also do this because they need to compete for the future scholarships or professions which focus on GPA as a criterion for entering the program or the profession. The fourth reason is the bad command of English. Students may lack excellent English skills. Instead of improving their language skills, they opt to cheat. The reason for this item to be fourth in the classification may be due to the high level of tolerance to students' English errors and mistakes by lecturers, so students tend not to improve their language skills. Lack of understanding of how to complete an assignment ranks fifth in the study. It is possible that students may not know the guidelines of completing the assignment. They reason may also refer to lack of knowledge, lack of intellectual skills, or lack of practical skills. However, instructors have to clarify the complete procedures of completing assignments. Authors' words rank sixth in the study. Some students fear to alter the meaning of the original words, so they keep the authors' words unchangeable. This is especially true to established words and phrases.

Low chance of being caught ranks seventh in the study. Some students do not care about getting caught. These students may believe that the benefits are more than the risks. This is a good reason for them to cheat. Some departments at the university may use the plagiarism detection systems, while other departments may not use these systems. This may also explain the students' behavior. The item of consideration 'penalties are minimal' ranks eighth in the research. These students feel that it is easy to cheat because rules are not enforced. The ninth and tenth reasons in the study are the items 'too much effort is required to paraphrase and quote' and everyone does it' successively. This group of students may be lazy or may have heavy academic load. These students need to be given guidelines in organizing their work as well as informing them about the importance of building their skills for the future careers they may seek.

The item 'never been taught how to paraphrase and quote' ranks eleventh in the study. Some students may feel the pressure to paraphrase the authors' words. This of course varies from one discipline to another. Some students largely maintain the writers' way of expressing ideas and structuring sentences. They borrow words and sentences from authors without acknowledgement. They do not use quotation marks to acknowledge the source of content. All in all, these students feel that their skills are weak. The last item 'taught to copy in school' does not rank high in the study. Though the percentage is the lowest for this item of consideration, but still it is disturbing to know that some students do believe that one of the reasons for academic dishonesty is 'taught to copy in schools'.

7. Conclusion

As plagiarism continues to threaten the trust and honesty of academic research, it is worth stressing that tools to prevent it have to be restated. Among these tools are raising awareness, clarity in the rules of disclosure and using plagiarism-detection software. It is also important not only to focus on punishment as a strategy to fight plagiarism, but rather to create a strong culture that promotes academic integrity and responsibility. Responsibility requires that students, professors and university management of Northern Cyprus Universities have to develop a more honest and coherent teaching/learning environment in order to maintain ethical standards throughout the universities. Finally, all parties related to scientific research have to look for new strategic choices that can help to confront academic misconduct.

Future research might focus on faculty members' perceptions and practices towards plagiarism and how they deal with this issue. Another study may explore the graduate students' perception towards academic dishonesty. Comparative studies in the region concerning the same issue are also encouraged. A cross-cultural study on the influence of Hofstede's cultural dimensions on the perceptions of plagiarism may also be applied.

Abstract

Understanding the needs, wants, and desires of university students in multi-cultural educational system is a critical issue for any university administration. The development of an efficient system of delivering a culturally sensitive curriculum requires the development of skills to understand how to satisfy students under the care of the university. Part of this understanding is to take into account the cultural differences between students. This research seeks to examine how Hofstede's cultural dimensions namely power distance and uncertainty avoidance can be related to students' satisfaction. This was examined by applying factor analysis and ordinary least squares (OLS) regression. Overall, the finding of the research will be used to determine how the students, professors and university management can coexist for a better education in North Cyprus. The research used a questionnaire as the main tool for gathering data. A sample of 637 students from the eight universities in North Cyprus was selected using the random sample procedure. While research findings indicated no relationship between high power distance and the satisfaction levels of university students, they indicated positive and significant relationship (robust relationship) between high uncertainty avoidance and the satisfaction levels of university students.

Keywords: Culture, power distance, uncertainty avoidance, satisfaction.

1. Introduction

There are eight universities in North Cyprus. They are Cyprus International University, Near East University, Eastern Mediterranean University, Girne American University, European University of Lefke, University of Mediterranean Karpasis, Istanbul Technical University, and Middle East Technical University. Six of them are local universities and two are the branches of the Middle Technical University in Ankara and İstanbul Technical University in Istanbul. Cyprus International University reported that the number of students in 2006 was 3545 and it rose to 7948 in 2014. As one can see, there is a growing number of students. They are from Turkey, Turkish Republic Northern Cyprus (TRNC), African, East Asian and Middle Eastern countries. Considering the number of all these students, Cyprus becomes a hub for the students from many different nationalities and cultures.

Despite all these figures and numbers, universities in North Cyprus are confronted with challenges such as bridging the cultural gap between the different nationalities. One of these pressing issues is students' satisfaction. Anderson and Zemke (1998) argue that it is very important for organizations to satisfy their customers. Satisfied customers will increase the organization's profit margin whilst dissatisfied customers

will weaken their growth. In contrast to the easily quantifiable improvements that are currently taking place in universities, little attention is given to the less quantifiable aspect of culture and its diversity. For instance, Eastern Mediterranean University (2012) has recognized in its strategic plan for 2012-2015 that one of the challenges is that comprehensive and effective policies should be formulated in coordination with all stakeholders. In the same plan, it is emphasized that one of the actions to be taken is the improvement and development of the campus infrastructure in line with the developments in educational technologies. The challenge of meeting the cross-cultural variations among students is receiving less attention, one can guess. However, it is recognized that education abroad offers an individual the opportunity to expand his/her experience and to connect with other international community. Builtjens and Noorderhaven (1996) hinted that leaders and managers at both the international and cross-cultural levels take decisions which consider their countries' norms and values. This fact leads to the necessity of training employees of multi-national organizations to be more culturally sensitive to the differences across cultures. As we are living in a globalized world, studying culture and its influences on education is a necessity.

This paper seeks to place culture into the debate of students' satisfaction, and calls for the universities to consider the cultures of students and adapt accordingly. This is to avoid potential decrease in numbers in the future or resistance by those who are not satisfied. McColl-Kennedy and Schneider (2000) point out that customers are important for any organization like other assets. Thus organizations have to monitor and manage customer satisfaction in an effective way so as to prosper and be more competitive with their rivals. This assertion holds also true for students as they are the customers of the universities. The paper also searches to determine how power distance and uncertainty avoidance can be taken into consideration by the universities in North Cyprus as cultural dimensions influencing their students' satisfaction. The paper also presupposes that knowledge of culture and its influence can be useful in Northern Cyprus universities. This is of course going beyond the design of both materials and platforms because they are not considering the impact of culture on students' satisfaction in the learning environment.

The research is conducted on both undergraduates and postgraduates students in order to investigate the power distance and uncertainty avoidance cultural dimensions on students' satisfaction. It is assumed that students studying in North Cyprus have variances in their satisfaction due to these two cultural dimensions. Accordingly, the students' perspectives are explored to learn the differences among students in terms of their satisfaction level. The present research argues that there is noticeably insufficient amount of research investigating the relationship between Hofstede dimensions, namely power distance and uncertainty avoidance and university students' satisfaction especially when students are coming from different nations. Overall, the findings of the research will be used to determine how the students, professors and university management can coexist for better future education in North Cyprus.

2. Literature Review

2.1 Theoretical Framework

Erez and Christopher (1993, p.43) states that "societies shape their collectives and aggregates according to the rules implied by culture." However, there are different definitions of culture. Schein (2004, p.17) defines culture as "a pattern of shared basic assumptions that was leaned by a group as it solved its problems of external adaptation and internal integration, that has worked well enough to be considered valid and, therefore, to be taught to new members as the correct way to perceive, think, and feel in relation to those problems." Hofstede (1980, p.13) defines culture as "the collective programming of the mind." Hofstede and Hofstede (2005) states that culture includes manners of thinking and behavior inherited and transmitted from one generation to another. These manners are elaborated through direct reciprocal action between, family members, friends, groups, work colleagues and community. In contrast to what has been introduced by Hofstede (1980) in terms of defining culture, Kuper (1999, p.299) describes culture as an issue of ideas and values with a combined shaping of mind. Interestingly, some other scholars go beyond that like Geertz (1993) who demonstrates that culture from a historical point of view is transmitted with different patterns of meanings characterized by symbols through which people communicate, maintain, and grow their knowledge, attitudes and perceptions toward life.

All these definitions and most probably others, despite some of the differences between them, show that human activity is influenced by culture. Monaghan and Just (2000) inform us that culture has a direct influence on human activity. Others have emphasized the deep roots of culture and its influences on values and beliefs, whether these beliefs and values are rational or not.
